November 2023

[1] Explosive Disposal Areas: East Burn Pads (EBPs), West Burn Pad Area (WBPA), North Burn Pads (NBPs), North Burn Pad Landfill (NBPLF), Fire Training Pit (FTP)

Executive Summary

This Remedial Investigation (RI) Report for Operable Unit 10 (OU-10) presents the results of RI activities for the environmental sites within the Explosives Disposal Area (EDA) at the Iowa Army Ammunition Plant (IAAAP), in Middletown, Iowa. The EDA consists of seven environmental sites within five areas: East Burn Pads (EBPs) (IAAP-012G), West Burn Pad Area (WBPA) (IAAP-032G, IAAP-003-R-01, and IAAP-005-R-01), North Burn Pads (NBPs) (IAAP-036G), North Burn Pad Landfill (NBPLF) (IAAP-037G), and Fire Training Pit (FTP) (IAAP-039G). The RI was conducted in accordance with the *Uniform Federal Policy–Quality Assurance Project Plan for Remedial Investigation at Iowa Army Ammunition Plant, Middletown, Iowa* (CH2M 2017a). This RI was completed under Delivery Order W912QR21F0421 of U.S. Army Corps of Engineers, Louisville District, Contract No. W912QR21D0019.

The IAAAP consists of 19,011 acres adjacent to Middletown, in Des Moines County, Iowa (Figure 1-1). It is approximately 8 miles west of Burlington, which with a population of 25,436, is the largest city in Des Moines County. The IAAAP is an active Joint Munitions Command facility currently operated by civilian contractor American Ordnance, LLC. The current mission of the IAAAP is to load, assemble, and pack ammunition items, including projectiles, mortar rounds, warheads, demolition charges, and munitions components such as fuses, primers, and boosters.

Due to explosives-contaminated surface water leaving the installation boundaries, the IAAAP was placed on the National Priorities List in August 1990. In September 1990, a Federal Facility Agreement was signed by the U.S. Environmental Protection Agency (USEPA) Region 7 and the U.S. Army; it became effective in December 1990. Through the Federal Facility Agreement, the U.S. Army works with the USEPA, with support provided by the Iowa Department of Natural Resources (IDNR). In accordance with the Federal Facility Agreement, "Site" refers to the IAAAP and any areas contaminated by the migration of hazardous substances from the IAAAP. The term "site" is used to refer to the environmental solid waste management units and areas of concern at the IAAAP (such as IAAP-012); this is consistent with Section IX.B of the 2018 Resource Conservation and Recovery Act (RCRA) Permit for the IAAAP.

The IAAAP was placed under the U.S. Department of Defense Installation Restoration Program (IRP), which follows the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA) process, as amended by the Superfund Amendments and Reauthorization Act. In July 2002, several areas of the IAAAP previously used by the former Atomic Energy Commission were designated by U.S. Army Corps of Engineers to be under the Formerly Utilized Sites Remedial Action Program (FUSRAP) and therefore were subsequently removed from the U.S. Department of Defense IRP (U.S. Army, 2007).

The IAAAP is currently divided into eight operable units (OUs), described below (USACE, 2016):

- OU-1 (soils): soil on the IAAAP other than those contaminated by use or testing of military munitions or by radiological constituents.
- OU-3 (offsite groundwater): groundwater outside of the IAAAP boundary.
- OU-4 (Inert Disposal Area): the Inert Disposal Area and its associated landfills, trenches, and sedimentation ponds.
- OU-5 (Military Munitions Response Program): Military Munitions Response Program sites.
- OU-6 (Onsite Groundwater): groundwater within the IAAAP boundary.
- OU-7 (Installation-wide): miscellaneous IAAAP sites not included in the other OUs.
- OU-8 (FUSRAP): sites contaminated by radiological and other contaminants by former Atomic Energy Commission activities and now being addressed by FUSRAP.

- OU-9 (construction): construction debris disposal sites.

OU-2 was also established originally for soil removal actions but was subsequently merged into OU-1. OU-4 was originally considered the installation-wide OU; however, in October 2009, the previously unaddressed areas of soil contamination were placed in OU-7, and the Inert Disposal Area remained in OU-4 (Tetra Tech, 2011a). Because the Compliance Cleanup (CC) sites were managed under RCRA, they do not currently fall within an OU.

To streamline the CERCLA process, three new OU divisions (OU-10, OU-11, and OU-12) are being proposed based on recommended remedial actions for the IAAAP sites. The OU-10 grouping is proposed for IAAAP groundwater sites in the EDA. The OU-11 grouping is proposed for miscellaneous IAAAP sites that warrant a NFA decision. The OU-12 grouping is proposed for IAAAP sites that were formally managed under the CC program. This RI report includes sites that are recommended for inclusion in the proposed OU-10 grouping.

The overall objectives of this RI were to update the conceptual site model for each site, assess the potential for unacceptable human health risks and hazards and the potential for ecological impacts (including identification of chemicals of concern [COCs] or chemicals of ecological concern), and recommend a path forward consistent with the *Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA, Interim Final* (USEPA, 1988). This report presents the results of RI activities for the IAAAP sites within the EDA.

Background values were established for metals in soil and groundwater at IAAAP; the same background data sets were used for both the human health and ecological risk evaluations. The soil background values were obtained from the *Reevaluation of Background Concentrations of Metals in Soil* (Jacobs, 2022). Groundwater background values were obtained from the *Evaluation of Background Concentrations of Metals in Groundwater* technical memorandum (CH2M, 2020a).

This RI document reflects certain procedural departures from the standard USEPA human health risk assessment (HHRA) process that the Army routinely applies at its installations (USEPA 1989). An example is the inclusion in the HHRA of onsite detected chemicals with concentrations that are either the same or less than those of their respective site-specific background concentrations (naturally occurring chemicals). Such an approach adds extraneous information into the HHRA process.

However, this background comparison method is consistent with Worksheet #14 of the *Uniform Federal Policy–Quality Assurance Project Plan for Remedial Investigation at Iowa Army Ammunition Plant, Middletown, Iowa* (CH2M, 2017a). Although inconsistent with the process the Army uses for background in the HHRA for their installations, this method complies with the requests from the USEPA in a memorandum from the USEPA Region 7 Remedial Project Manager to the IAAAP Project Manager (USEPA, 2019).

IAAAP Site-specific Descriptions

This report presents the results of RI activities for seven environmental sites (IAAP-012G, IAAP-032G, IAAP-003-R-01, IAAP-005-R-01, IAAP-036G, IAAP-037G, and IAAP-039G) within the following five areas of the EDA:

- **East Burn Pads (EBPs) (IAAP-012G):** This RI report addresses groundwater at the EBPs area, which encompasses 12 acres and is located in the northeast portion of the IAAAP facility (Figure 5.4-1). Soil at the EBPs is addressed under the remedy for OU-1 (IAAP-012) (Leidos, 2018). The EBPs are immediately east of Spring Creek. The EBPs previously contained eight burning pads, and this area was active between 1949 and 1982 for operations that included open burning of explosives-contaminated metals, propellants, explosives, and pyrotechnics-contaminated materials. Operations ceased at the EBPs in 1982 once the Explosives Waste Incinerator (EWI) was constructed, and there are no remaining structures in this area.

- **West Burn Pad Area (WBPA) (IAAP-032G, IAAP-003-R-01, and IAAP-005-R-01):** This RI report addresses groundwater, surface water, and sediment at the WBPA. Soil at the WBPA is addressed under the remedies for OU-1 (IAAP-032) (Leidos, 2018). The WBPA encompasses approximately 14 acres within the Spring Creek watershed, immediately west of Spring Creek (Figure 5.4-1). The WBPA was used for demilitarization by open burning, which was performed at former burn pads located within the WBPA. Burning operations were also performed within metal cages at the Burn Cages. Waste material from the burning operations at the burn pads and burn cages were disposed of at the WBP Landfill and Burn Cage Ash Landfill, located in the western and eastern portions of the WBPA, respectively. The WBPA was also used for munitions response activities, to flash explosives-contaminated metal parts and store salvageable metal parts. The WBPA was active starting in 1947 and operations ceased at the WBPA in 1982 once the EWI was constructed. The Atomic Energy Commission also conducted activities at the WBPA between 1947 and 1975. Two buildings are present at the WBPA, Building BG-13 and office Building 500-183, and a road runs through the center of the WBPA connecting to the EBPs. An underground viewing bunker is present near Building 500-183.
- **North Burn Pads (NBPs) (IAAP-036G):** This RI report addresses groundwater at the NBPs, which encompasses approximately 4 acres and is located north of the WBPA in the Spring Creek watershed (Figure 5.4-1). Soil at the NBPs is addressed under the remedy for OU-1 (IAAP-036) (Leidos, 2018). The NBPs consisted of two former earthen burn pads, which were active between 1968 and 1972 for open burning of lead azide and gun powder. A former 275-gallon diesel-refueling station was also present at the base of one of the burn pads, Pad 2-N. There are no remaining structures onsite.
- **North Burn Pad Landfill (NBPLF) (IAAP-037G):** This RI report addresses groundwater at the NBPLF, which encompasses approximately 3 acres and is located 800 feet north of the NBPs in the Spring Creek watershed (Figure 5.4-1). Soil at the NBPLF is addressed under the remedy for OU-1 (IAAP-037) (Leidos, 2018). The NBPLF consists of a former landfill measuring 60 by 470 feet that was capped with clay during cleanup operations in 1980. Residual ash and flashed cans, containers, and construction debris from the NBPs and EDA were disposed of at the NBPLF. One building, BG-199-4, is present at the NBPLF and is currently used as a breakroom for American Ordnance staff. Additional activities at this site include waste disposal of waste slightly contaminated with explosives and RCRA 90-day hazardous waste storage of paint filters, which are shipped offsite for disposal.
- **Fire Training Pit (FTP) (IAAP-039G):** This RI report addresses groundwater at the FTP area, which includes the former training pit and adjacent areas and facilities to the east and southeast (Figure 5.4-1). Soil at the FTP area is addressed under the remedy for OU-1 (IAAP-039) (Leidos, 2018). The FTP encompasses approximately 2 acres and includes a former smoke trainers vault (Building 200-30); two former burn pits located southeast of the smoke trainers vault; and a former disposal pit located between the smoke trainers vault and the burn pits. The FTP area was used between 1970 and 1988 for firefighting training operations that consisted of placing solvents or fuels in 55-gallon drums within the FTP, igniting the solvents, and then extinguishing the fire using fire suppression foam. Note that the FTP was identified as an area of potential interest (AOPI) during a Preliminary Assessment for per- and polyfluoroalkyl substances (PFAS) at IAAAP (Arcadis, 2020). The PFAS AOPIs are currently under a site inspection, and therefore PFAS is not a component of this OU-10 RI.

Remedial Investigation Conclusions

The following RI and risk assessment conclusions were derived for each IAAAP area.

EBPs (IAAP-012G)

Potential sources of contamination at the EBPs include historical activities associated with open burning of explosives-contaminated metals, propellants, explosives, and pyrotechnics-contaminated materials. Available documentation does not indicate that petroleum fuels or other liquid accelerants were used for open burning operations. Explosive powder that was used to initiate the flashing was spread on top of materials placed on the burn pads. Live ordnance was not demilitarized (Tetra Tech, 2006). Scrap metal was recovered for offsite recycling, and ash and other debris were disposed of offsite. Operations at the EBPs ceased once the EWI was constructed in 1982.

Based on historical site operations and a comparison of the most current concentration data to site characterization project action limits (PALs) and background threshold values (BTVs), only Royal Demolition Explosive (RDX) was identified as a potential site-related chemical of interest in groundwater. RDX groundwater contamination is present as one large plume, which exists primarily within the overburden aquifer. It was detected above its site characterization PAL in only four overburden and shallow bedrock monitoring wells during the latest sampling events (EBP-MW3, EBP-MW4, EBP-MW5, and EDA-2). Although RDX concentrations in three out of the four wells have decreased since late 2007, increasing trends at monitoring wells EBP-MW4 and EDA-3, located at the leading edge of the plume, may be indicative of some plume migration. However, the overburden aquifer is absent in the western portion of the site, where it pinches out and bedrock outcrops to the surface. Along with the slow groundwater flow velocity, this may be limiting the extent of plume migration. As such, no RDX exceedances have been observed in the most downgradient monitoring wells at the site. The RDX plume is considered to be laterally and vertically delineated.

The soil removal that was completed in 1999 is assumed to have removed the bulk of RDX contamination that could be a source to groundwater. Although initial confirmation sampling showed RDX concentrations above the OU-1 leachability-based remediation goal (RG) (1.3 mg/kg) at Pads 1E, 2E, 4E, 5E, 6E, and 8E, an additional 1 to 2 feet of soil was excavated in these areas following the confirmation sampling. Because a second round of confirmation sampling was not conducted, it is unknown whether RDX concentrations in soil still exceeded the leachability goal at the EBPs.

The HHRA did not identify any unacceptable risks or hazards for future residential receptors exposed to site-related chemicals in soil or groundwater at the EBPs. The Ecological Risk Assessment (ERA) concluded that no adverse effects to ecological receptors exist at the EBPs, given the lack of complete exposure pathways for ecological receptors.

WBPA (IAAP-032G)

Potential sources of contamination at WBPA include historical activities associated with open burning demilitarization activities and burning and disposal of dunnage. Open burning was performed on a variety of munitions debris and related materials, including explosives-contaminated metals parts and inert and explosives-contaminated packaging. Recoverable metal was segregated for offsite recycling and reuse subsequent to burning. Land disposal was performed at onsite landfills for other wastes from burning operations, including ash, paper, wood, and metal cans. Burning and disposal operations at the WBPA ceased after the EWI was constructed in 1982.

Based on historical site operations and a comparison of the most current concentration data to site characterization PALs and BTVs, three explosives (RDX, 2,6-dinitrotoluene, and 1,3-dinitrobenzene), four volatile organic compounds (VOCs) (1,1,2-trichlorotrifluoroethane [Freon 113], 1,1-dichloroethane, 1,1-dichloroethene, and trichloroethene [TCE]) and one metal (arsenic) were identified as potential site-related chemicals of interest in groundwater. RDX is the most extensive chemical, and the other explosives are present within the RDX plume extents. RDX is present primarily as one large plume, which exists primarily within the overburden and shallow bedrock aquifers. The soil removals are assumed to have removed the bulk of RDX contamination that could be a source to groundwater. However, confirmation samples collected in 2000 from the four excavation areas (WBP Landfill, Pad 2-W, Burn Cage Ash Landfill, and Pad 1-W) indicated that RDX was still present above OU-1 leachability RGs (ECC, 2001), which could be a continuing source at the WBPA. VOCs are present in three plumes at the WBPA, two in the northern portion of the WBPA and one in the eastern portion of the WBPA. Of note is a large VOC plume that extends into the southeastern corner of the WBPA; however, this plume is associated with the FTP site (IAAP-039). Arsenic exceeded its PAL and BTV at only one well in 2019.

A groundwater treatability study was conducted from 2005 through 2009 in the northwest portion of the RDX plume, near WBP-TTMW-05B, and in the southeast portion of the RDX plume, near WBP-99-3, where historically the highest RDX and Freon 113 concentrations had been observed. Stable and decreasing RDX concentrations are north and east of the RDX plume; however, some increasing trends may be indicative of some plume migration or rebound following the treatability study injections. However, the slow groundwater flow velocity should be limiting the extent of plume migration. The RDX plume is considered to be laterally and vertically delineated for this RI.

In surface water, only dissolved aluminum was detected above its site characterization PAL and BTV in 2019, downstream of the EDA. Dissolved aluminum was not detected upstream of the EDA in 2019. No site-related chemicals of interest were identified for sediment.

The HHRA identified potentially unacceptable risks for future hypothetical residential receptors exposed to site-related chemicals in groundwater at the WBPA, including VOCs, explosives, and arsenic. The HHRA also identified potentially unacceptable risks associated with exposure to Freon 113, 1,3-dinitrobenzene, 2,6-dinitrotoluene, arsenic, chloroform, dichlorodifluoromethane, RDX, and TCE for current and/or future site workers and to TCE for construction/utility workers. The HHRA concluded that there are no unacceptable risks or hazards for hypothetical residents from exposure to surface water or sediment at the WBPA.

The ERA concluded that no adverse effects to ecological receptors exist at the WBPA. Surface water and sediment data were evaluated in the 2022 Watershed ERA (Appendix I) for the Spring Creek watershed. From the Screening Level Ecological Risk Assessment, copper and silver in sediment were identified as chemicals of potential ecological concern (COPECs); these COPECs were carried forward into the Baseline Ecological Risk Assessment. No chemicals were identified as COPECs in surface water. Following the weight-of-evidence evaluation, no COPECs were identified for Spring Creek. The recommendation of NFA for the Spring Creek watershed based on the results of the Watershed ERA means that no ecological impacts are expected at the WBPA.

NBPs (IAAP-036G)

Potential sources of contamination at NBPs include historical activities associated with open burning activities, including of lead azide and gunpowder. Incomplete combustion of explosives compounds and metals from ash released to soil may have leached into groundwater.

Based on historical site operations and a comparison of the most current concentration data to site characterization PALs and BTVs, no contaminants were detected as potential site-related chemicals of interest in groundwater. Historically, explosives, VOCs, and metals were identified as chemicals of interest in groundwater at the NBPs; however, metals and VOCs have been detected below screening criteria since 2000, and no explosives were detected above their respective PALs in 2019. Freon 113 was detected in groundwater in one well in 2019; however, concentrations were below the site characterization PAL, which differs from the screening value used for HHRA. This well (JAW-13) is located near the southern boundary of the NBPs and may represent the northern edge of VOCs observed in groundwater at the WBPA. Given the lack of RDX in groundwater during the current RI, the soil removal that was completed in 1998 is assumed to have removed RDX contamination that could be a source to groundwater.

The HHRA identified potentially unacceptable hazards (hazard index [HI] is greater than 1) from exposure to Freon 113 (HI = 5 for adult and child future hypothetical resident) through a potential vapor intrusion pathway. Therefore, this analyte was identified as a potential vapor intrusion COC for future hypothetical residents. However, the current and expected future Land Use of the IAAAP is Commercial/Industrial so future exposures to residents is not likely. The ERA concluded that no adverse effects to ecological receptors exist at the NBPs, given the lack of complete exposure pathways for ecological receptors.

NBPLF (IAAP-037G)

Potential sources of contamination at NBPLF include historical activities associated with releases to the surface and subsurface as a result of historical site operations, including burial of waste within the NBPLF. The NBPLF was formerly used for disposal of ash residue from NPB burning operations as well as flashed cans, containers, and construction debris. The site is no longer an active landfill and is currently used for temporary waste storage, including slightly contaminated explosives waste, which is placed in dumpsters and shipped offsite for disposal at approved facilities.

Based on historical site operations and a comparison of the most current concentration data to site characterization PALs and BTVs, only one explosive (RDX) was identified as a potential site-related chemical of interest in groundwater. RDX contamination has been observed as two small plumes at the NBPLF. The main RDX plume is present at the NBPLF to the east of the former landfill and is restricted to within the shallow bedrock. The second RDX plume is isolated and was historically defined by former overburden well JAW-625. However, RDX was not detected in nearby NBPLF-MW1 during the current RI. Therefore, RDX concentrations in this second plume may have attenuated below the site characterization PAL. Explosives were detected above their site characterization PALs in only three shallow bedrock monitoring wells in 2019 and 2020 (JAW-627, NBPLF-MW4, and NBPLF-MW6). RDX concentrations at JAW-627 have been increasing since 2001. The soil removal that was completed in 1998 is assumed to have removed the bulk of RDX contamination that could be a source to groundwater. Confirmation sampling showed one RDX concentration (2.5 mg/kg) within the former NBPLF above the OU-1 leachability-based RG (1.3 mg/kg). However, the increasing RDX concentrations at JAW-627 indicate there may still be a source of RDX leaching to groundwater from the former landfill. Increasing RDX concentrations may also be indicative of continued plume migration. No RDX was detected in surface water samples collected in 2018, due northeast and southeast of the NBPLF, which indicates that the eastern plume is defined. The RDX is considered to be laterally and vertically delineated for this RI.

The HHRA did not identify any unacceptable risks or hazards for future residential receptors exposed to site-related chemicals in soil or groundwater at the NBPLF. The ERA concluded that no adverse effects to ecological receptors exist at the NBPLF, given the lack of complete exposure pathways for ecological receptors.

FTP (IAAP-039G)

Potential sources of contamination at FTP area include historical activities associated with chemical use, burning, and disposal. The former training pit was used for firefighting training operations between 1982 and 1987. Two smaller pits existed to the north of the main training pit: one disposal pit contained trash and debris, and another pit was used to burn wastes similar to those used in the firefighting practices in the main pit, though this disposal pit was not used for firefighter training.

Based on historical site operations and a comparison of the most current concentration data to site characterization PALs and BTVs, VOCs, explosives, and arsenic were identified as potential site-related chemicals of interest in groundwater. Numerous VOCs associated with chlorinated solvents, fuels, and associated breakdown products have been detected at the FTP. Historically, 1,1-dichloroethene and 1,1-dichloroethane have exceeded their PALs with the greatest frequency. VOC groundwater contamination is present as one large plume, with the majority of VOC contamination within the footprint of the former main training pit and a soil removal area. The explosives plume is isolated to the sump well (SA-99-1), located within the soil removal area. Arsenic groundwater contamination was observed within the vicinity of the former training pit and soil removal area and arsenic concentrations have been fairly consistent in this area since 2001. The slow groundwater flow velocity and natural attenuation processes are likely helping to limit the extent of plume migration. As such, no contaminant exceedances have been observed in the most downgradient monitoring wells in this area. The VOC plume is considered to be laterally and vertically delineated for this RI.

The HHRA identified potentially unacceptable risks for future residential receptors exposed to site-related chemicals in groundwater at the FTP, including VOCs, explosives, and arsenic. The HHRA also identified potentially unacceptable risks associated with exposure to 1,1-dichloroethane, 1,1-dichloroethene, 1,2-dichloroethane, 4-amino-2,6-dinitrotoluene, arsenic, benzene, cis-1,2-dichloroethane, ethylbenzene, methylene chloride, naphthalene, TCE, and vinyl chloride for site workers; and benzene, naphthalene, methyl ethyl ketone, methyl isobutyl ketone, methylene chloride, tetrachloroethene, toluene, TCE, vinyl chloride, m,p-xylene, and o-xylene for construction/utility workers. The ERA concluded that no potential adverse effects to ecological receptors exist at the FTP, given the lack of complete exposure pathways for ecological receptors.

Recommendations

It is recommended that the five IAAAP groundwater sites (IAAP-012G, IAAP-032G, IAAP-036G, IAAP-037G, and IAAP-039G) included in this RI report be transferred to a new OU (OU-10). The new OU-10 grouping will include Environmental Restoration sites located within the EDA. Based on the RI conclusions and results of human health risk assessments and ecological risk assessments, the following is also recommended:

- Conduct a Feasibility Study (FS) for three sites (IAAP-032G, IAAP-036G, and IAAP-039G) associated with groundwater at the WBPA, NBPs, and the FTP to evaluate remedial alternatives to address the unacceptable risks or hazards from site-related COCs in groundwater. If appropriate, it is recommended that TCE reductive degradation products (such as cis-1,2-DCE and vinyl chloride) be included in the monitoring plans of the FS remedial alternatives. NFA is warranted for surface water and sediment at the WBPA under IAAP-032G.

- Propose a NFA decision in a Proposed Plan as the preferred remedy for one site (IAAP-012G associated with groundwater at the EBPs. This recommendation is based on the fact that site-related chemicals do not pose potentially unacceptable risks or hazards. This IAAAP site can subsequently be closed under an NFA Record of Decision for OU-10.

- Conduct a Supplemental Remedial Investigation (SRI) for one site (IAAP-037G). The results of the RI and risk assessments indicate that site-related chemicals do not pose potentially unacceptable risks or hazards. However, because increasing RDX concentrations have been observed in groundwater at JAW-627 and not all RDX in soil was removed at this site to the OU-1 leachability RG, additional groundwater monitoring at JAW-627 is recommended to provide a further line of evidence that a NFA decision is warranted for the NBPLF.

- Retain the two munition IAAAP sites (IAAP-003-R-01 and IAAP-005-R-01) under OU-5. These two Military Munitions Response Program sites have already been closed as NFA for munitions and explosives of concern (MEC) and munitions chemicals (MC) under the OU-5 ROD (CB&I, 2014); therefore, no additional action is needed for these sites and they can remain closed. These recommendations for the OU-5 sites can be documented in the next five-year review report for IAAAP, which includes the IRP OUs with remedies in place (OU-1, OU-3, OU-4, and OU-5).

- Repair the new EDA staff gauges to obtain accurate measurements in the future. Between staff gauge installation in 2018 and the 2019 RI gauging event, the three new staff gauges (EDA-1 through EDA-3) were damaged.

The recommendations for the EDA sites are summarized below:

RI Recommendation	Army Environmental Database Information	
	Site Number	**Site Name**
FS for groundwater under OU-10	IAAP-036G	North Burn Pads Groundwater
	IAAP-039G	Fire Training Pit Groundwater
FS for groundwater and NFA for surface water and sediment under OU-10	IAAP-032G	West Burn Pad Area Groundwater
NFA for groundwater under OU-10	IAAP-012G	East Burn Pads Groundwater
SRI for groundwater under OU-10	IAAP-037G	North Burn Pad Landfill Groundwater
NFA under OU-5[a]	IAAP-003-R-01	West Burn Pads
	IAAP-005-R-01	West Burn Pads South of Road

[a] NFA is already documented in the OU-5 ROD.

WBPs	West Burn Pads

SECTION 1

Introduction

This Remedial Investigation (RI) report presents the results of RI activities for the environmental sites within the Explosives Disposal Area (EDA) at the Iowa Army Ammunition Plant (IAAAP), in Middletown, Iowa. IAAAP is an active Joint Munitions Command facility currently operated by civilian contractor American Ordnance, LLC (AO). In accordance with the Federal Facility Agreement (FFA), "Site" refers to the IAAAP and any areas contaminated by the migration of hazardous substances from the IAAAP. The term "site" is used to refer to the environmental solid waste management units and areas of concern at the IAAAP (such as IAAP-012G); this is consistent with Section IX.B of the 2018 Resource Conservation and Recovery Act (RCRA) Permit for the IAAAP.

The EDA is shown on Figure 1-1; the following five areas are included in this OU-10 RI report:

- East Burn Pads (EBPs)
- West Burn Pad Area (WBPA), which includes:
  - Burn Cages site
  - Burn Cage Ash Landfill
  - West Burn Pads (WBPs)
  - WBPs Landfill
  - WBPs munitions response site (MRS)
  - WBPs South of Road (WBPS) MRS
- North Burn Pads (NBPs)
- North Burn Pad Landfill (NBPLF)
- Fire Training Pit (FTP)

The Contaminated Waste Processor (CWP) (IAAP-024) and the Explosives Waste Incinerator (EWI) (IAAP-025) are also located within the EDA, but they are being addressed under the RI reports for OU-12 (CH2M, 2021a) and OU-11 (CH2M, 2021b), respectively. The CWP is being addressed under OU-12 since it is a multi-media (soil and groundwater) site that was previously managed under the Compliance Cleanup (CC) program. The EWI is being addressed under OU-11 since it is a multi-media (soil and groundwater) site that No Further Action (NFA) is warranted.

This OU-10 RI was conducted in accordance with the *Uniform Federal Policy–Quality Assurance Project Plan for Remedial Investigation at Iowa Army Ammunition Plant, Middletown, Iowa* (UFP-QAPP) (CH2M, 2017a). This work was completed under Delivery Order 0006 of U.S. Army Corps of Engineers, Louisville District (USACE), Contract W912QR-12-D-0005.

1.1 Remedial Investigation Objectives

Several investigations have been conducted at the IAAAP since the 1980s to evaluate the nature and extent of chemicals in site media. The overall objectives of this RI are to update the conceptual site model (CSM) for each site, assess the potential for unacceptable human health risk and hazard and for ecological impacts—that is, identify chemicals of concern (COCs) or chemicals of ecological concern (COECs)—and recommend a path forward consistent with the *Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA, Interim Final* (USEPA 1988). To meet the objectives, new and previously collected data (as appropriate) were evaluated to assess the potential for a contaminant release. The data were used to assess the nature and extent of contamination, evaluate chemical fate and transport, and estimate potential risks and hazards posed by site-related contamination to human health and the environment. The Human Health Risk Assessment (HHRA) approach is discussed in Section 4.3.1, and detailed supporting information is included in Appendix A. The Ecological Risk Assessment (ERA) approach is discussed in Section 4.3.2. The updated CSM, which incorporates information onsite characteristics, nature and extent of contamination, fate and transport, the HHRA, and the ERA exposure routes collectively, was used to identify whether a Feasibility Study (FS) or NFA determination is warranted at each site.

1.2 Installation Background

1.2.1 IAAAP Description

The IAAAP consists of 19,011 acres adjacent to Middletown, in Des Moines County, Iowa. It is approximately 8 miles west of Burlington, and with a population of 25,436, is the largest city in Des Moines County. The installation is bordered by Highway 34 to the north, upland agricultural farms to the east and west, and the Skunk River Valley to the south. The installation layout is shown on Figure 1-1.

The IAAAP is an active Joint Munitions Command facility currently operated by civilian contractor American Ordnance, LLC. The current mission of the IAAAP is to load, assemble, and pack ammunition items, including projectiles, mortar rounds, warheads, demolition charges, and munitions components such as fuses, primers, and boosters. Approximately one third of the IAAAP property is occupied by active or formerly active production or storage facilities. The IAAAP consists of production lines, landfills, disposal areas, burn areas, a demolition area, and a fire training area. The remaining land is either woodlands or property leased for agricultural usage. The locations of the IAAAP sites are shown on Figure 1-1.

1.2.2 IAAAP Operational History

The principal mission of IAAAP over time has been to load, assemble, and pack operations for a variety of conventional ammunition and fusing systems. IAAAP was constructed in November 1940, as the Iowa Ordnance Plant and started production in 1941. Production was stopped in 1945, when World War II ended. The plant resumed its ammunition manufacturing mission in 1949, prior to the Korean War. In 1950, in response to the Korean conflict, production increased dramatically. From 1947 through mid-1975, the former Atomic Energy Commission occupied facilities on the site for nuclear weapons and non-nuclear additional weapon-assembly operations; those facilities then reverted to Army control in 1975 (H&S Environmental, 2016).

The IAAAP has a National Pollutant Discharge Elimination System permit (Permit 2900900) in place as part of its operations. In 1995, permitted outfalls were reported at Lines 1, 2, 3, 5, and 800, which discharged to Brush Creek, and at Line 3A, which discharged to the Skunk River. At that time, combined Royal Demolition Explosive (RDX) plus hot melt explosive (HMX) discharge concentrations were as high as 1,410 micrograms per liter (µg/L), and 2,4,6-trinitrotoluene (TNT) discharge concentrations were as high as 2,540 µg/L (JAYCOR 1996).

The 2001 permit allowed discharge of effluent with explosives (TNT and RDX + HMX) from 11 outfalls at the facility. The permit was updated in 2020 and currently allows for seven outfalls to discharge effluent with explosives with a 30-day average of 0.75 milligrams per liter (mg/L) and daily maximum discharge of 2.25 mg/L for RDX + HMX, and with a 30-day average of 0.33 mg/L and daily maximum discharge of 1.00 mg/L for TNT (Figure 1-2). Explosives are not included on the updated permit for five outfalls.

1.2.3 IAAAP Regulatory Setting

Due to explosives-contaminated surface water leaving the installation boundaries, the IAAAP was added to the National Priorities List in August 1990. In September 1990, an FFA was signed by USEPA Region 7 and the U.S. Army; it became effective in December 1990. The 1990 FFA identified 30 RCRA Solid Waste Management Units (SWMUs) at the facility. The 2018 RCRA Permit (USEPA, 2018a) stated that the SWMUs listed in the 1990 FFA are being integrated into the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA) sites; the integration plan is currently being developed. Through the FFA, the U.S. Army works with USEPA, with support provided by Iowa Department of Natural Resources (IDNR). The IAAAP was placed under the U.S. Department of Defense (DoD) IRP, which follows the CERCLA process, as amended by the Superfund Amendments and Reauthorization Act.

In July 2002, several areas of the IAAAP previously used by the former Atomic Energy Commission were designated by USACE to be under the Formerly Utilized Sites Remedial Action Program (FUSRAP) and therefore were subsequently removed from the DoD IRP (U.S. Army, 2007). Investigations continued at the FUSRAP areas, and an additional FFA for the FUSRAP sites was finalized in August 2006 (USACE, 2011).

The IAAAP is currently divided into eight operable units (OUs) (USACE, 2016):

- OU-1 (Soils): soil on the IAAAP other than that contaminated by use or testing of military munitions or by radiological chemicals.
- OU-3 (Offsite Groundwater): groundwater outside of the IAAAP boundary.
- OU-4 (Inert Disposal Area): the Inert Disposal Area and its associated landfills, trenches, and sedimentation ponds.
- OU-5 (Military Munitions Response Program): Military Munitions Response Program (MMRP) sites.
- OU-6 (Onsite Groundwater): groundwater within the IAAAP boundary.
- OU-7 (Installation-wide): miscellaneous IAAAP sites not included in the other OUs.
- OU-8 (FUSRAP): sites contaminated by radiological and other contaminants by former Atomic Energy Commission activities and now being addressed under FUSRAP.
- OU-9 (Construction Debris Areas): construction debris disposal sites.

OU-2 was also established originally for soil removal actions but was subsequently merged into OU-1. OU-4 was originally considered the installation-wide OU; however, in October 2009, the previously unaddressed areas of soil contamination were placed in OU-7, and the Inert Disposal Area remained in OU-4 (Tetra Tech, 2011). Because the CC sites were managed under RCRA, they do not currently fall within an OU.

Several of the sites at the IAAAP have been investigated under more than one OU, the FUSRAP, and/or the RCRA CC program. To streamline the CERCLA process, three new OU divisions (OU-10, OU-11, and OU-12) are being proposed based on recommended remedial actions for the IAAAP sites. The OU-10 grouping is proposed for IAAAP groundwater sites in the EDA. The OU-11 grouping is proposed for miscellaneous IAAAP sites that warrant a NFA decision. The OU-12 grouping is proposed for IAAAP sites that were formally managed under the CC program.

1.2.4 IAAAP Sites Included in This Report

The Headquarters Army Environmental System includes 75 IRP sites at the IAAAP. Originally, only the 30 SWMUs that were identified in the FFA were included (IAAP-001 through IAAP-030). The U.S. Army Toxic and Hazardous Material Agency's 1991 draft final *Potential Areas of Concern Supplement* (USATHAMA

1991) designated IAAAP sites IAAP-031 through IAAP-043. Between 1999 and 2003, IAAAP sites IAAP-044 through IAAP-047 were added to address Pinkwater Lagoon, the former fuel station underground storage tanks, off-installation groundwater, and the Central Test Area. In addition, in 2002, nine groundwater-designated sites, or “G” sites, were created to facilitate management of groundwater at areas known to have groundwater contamination. To further separate and manage IAAAP areas by OU, 24 additional IRP sites with a “G” designation were created in the Army database in 2012.

Included in this report are seven IAAAP sites within five areas at the EDA. The sites are listed below with a summary of their Army Environmental Database or RCRA Compliance Cleanup site name and number, a brief description, the OU that the IAAAP site is currently associated with, and the RI report section where the IAAAP site is discussed in more detail.

IAAAP Area (Abbreviation for RI Report)	Army Environmental Database Site Number	Current Operable Unit	Media Addressed in RI Report	Brief Site Description	RI Report Section
East Burn Pads (EBPs)	IAAP-012G	OU-6	Groundwater	Encompasses approximately 12 acres in the northeastern portion of the IAAAP facility and was formerly used for open burning of explosives-contaminated materials.	5.1
West Burn Pad Area (WBPA)	IAAP-032G IAAP-003-R-01 IAAP-005-R-01	OU-6 OU-5	Groundwater Surface Water Sediment	Encompasses approximately 14 acres in the northeastern portion of the IAAAP facility and was formerly used for demilitarization by open burning. Waste materials from burning activities were disposed of at two onsite landfills.	5.2
North Burn Pads (NBPs)	IAAP-036G	OU-6	Groundwater	Encompasses approximately 4 acres in the northeastern portion of the IAAAP facility and was formerly used for open burning of lead azide and gun powder.	5.3
North Burn Pad Landfill (NBPLF)	IAAP-037G	OU-6	Groundwater	Encompasses approximately 10 acres in the northeastern portion of the IAAAP facility and was a former landfill used for disposal of waste materials from burning activities at the NBPs.	5.4
Fire Training Pit (FTP)	IAAP-039G	OU-6	Groundwater	Encompasses approximately 2 acres in the northeastern portion of the IAAAP facility and was formerly used for fire training and to store explosives prior to incineration at the EWI.	5.5

SECTION 2

IAAAP Environmental Setting

2.1 Climate

Des Moines County has a typical Midwestern climate of hot/humid summers and cold/wet winters. According to the National Weather Service (2020), between 1981 and 2010, the mean annual temperature in this area was 53°F. The average annual precipitation in this area is 38.48 inches. During winter, precipitation frequently occurs as snow, and during the rest of the year it is mainly rain, often heavy. The highest rainfall amounts tend to occur between May and August. Snowmelt during spring, combined with frozen or saturated soil conditions that reduce infiltration, can result in high runoff and substantial erosion. In addition, severe thunderstorms in summer can also result in a high volume of precipitation over a short period of time and create high runoff volumes (H&S Environmental, 2016).

2.2 Topography

IAAAP is in the Southern Iowa Drift Plain. The highest elevation in the county, 862 feet above mean sea level (amsl), is located about 13 miles north of IAAAP, near the town of Yarmouth, Iowa. The lowest elevation, about 520 feet amsl, is located where the Skunk River enters the Mississippi River at the southeastern boundary of the county. Vertical reliefs between lowlands and adjoining uplands generally range from 50 to 120 feet.

Where it is not dissected by drainages, the topography at IAAAP is generally flat in the uplands and slopes gently toward the south. Elevations at IAAAP range from 732 feet amsl along the northern extent of the installation to about 544 feet amsl throughout the extensive southern area of Long Creek and Skunk River.

2.3 Surface Water Hydrology

The IAAAP contains five different hydrologic watersheds: Brush Creek, Little Flint Creek, Long Creek, Skunk River, and Spring Creek (Figure 2-1). A watershed is an area of land that drains to a common water outlet, such as a creek or ocean. These four creeks and Skunk River are the common water outlets, or water features to which a watershed drains, present at IAAAP. A watershed includes all the surface water (that is, lakes, reservoirs, and wetlands) within the defined land area. Surface water does not cross watershed boundaries. That is, surface water in drainages in the Brush Creek watershed will not flow into the Long Creek watershed (Figure 2-1). Groundwater in the overburden aquifer (Figure 2-2) and bedrock aquifer (Figure 2-3) are also influenced by the watershed boundaries; however, where the aquifer is deeply confined, groundwater is likely to ultimately discharge to a larger watershed, such as a large river, rather than to a small tributary. At the IAAAP, the Brush Creek and the Long Creek watersheds drain most of the installation.

The five watersheds are summarized as follows:

- The Brush Creek watershed is in the east-central portion of the IAAAP and is fed by intermittent tributaries. Water that drains into Brush Creek flows generally south and exits at the southeastern boundary of the IAAAP. Approximately 3 miles beyond the IAAAP, the creek flows into the Skunk River (Tetra Tech, 2006).
- The Little Flint Creek watershed comprises a very small area in the north-central portion of the facility. Water that drains into this watershed flows northward, away from the installation, before turning south again and joining the Spring Creek watershed (Tetra Tech, 2006).

- The Long Creek watershed is in the west-central portion of the IAAAP and is fed by unnamed perennial tributaries from the north and many small intermittent tributaries (Tetra Tech, 2006). Long Creek has been dammed to form George H. Mathes Lake, within the central area of the IAAAP. Water that drains into Long Creek generally flows east-southeast and south and exits at the southeastern boundary of the installation. Approximately half a mile beyond the IAAAP, the creek flows into the Skunk River (Tetra Tech, 2006).
- The Spring Creek watershed is in the eastern portion of the IAAAP and is fed by perennial tributaries from the north and east and several smaller intermittent tributaries (Tetra Tech, 2006). Water that drains into Spring Creek generally flows south and exits at the southeastern boundary of the IAAAP. The creek eventually discharges into the Mississippi River.
- The Skunk River watershed is in the southwest corner of the IAAAP and is primarily fed by small intermittent tributaries (Tetra Tech, 2006). This watershed drains to Skunk River, which is just outside the southwest boundary of the IAAAP. The river then flows generally east-southeast.

Streamflow can fluctuate over any given year due to many factors. The amount of precipitation varies seasonally, as described in Subsection 2.1. Snow typically stays where it falls, and therefore streamflow may decrease during this period. However, if the ground is frozen when the snow melts, then runoff to the streams may increase temporarily because water cannot infiltrate into the ground. When evapotranspiration is high, as in the early spring or summer, streamflow can decrease because more water is being taken up by plants and released to the atmosphere. Streamflow is also impacted by seasonal fluctuations in the water table elevation of the surficial groundwater aquifer.

The creeks at the IAAAP have been observed to be "gaining" and "losing" streams. A gaining stream is one that gains water from groundwater, typically because the stream channel bottom is lower than the groundwater table. Therefore, groundwater will discharge to the water body. In contrast, a losing stream is one that loses water to groundwater. It is common for a creek to be a gaining stream in one area and a losing stream in another area. Also, creeks and rivers may be gaining at one time of the year and losing in another time of the year.

2.4 Soil

With exception of developing soil associated with rivers and drainages, soil on IAAAP belongs to either the Mollisols or Alfilsols soil orders. Mollisols are a relatively fertile soil and are characterized by a soft surface character, a high base saturation (generally indicative of fertile soil), and a dark color due to abundant humus. Alfilsols are also a relatively fertile soil with moderate to high base saturation. Agriculture plays a major role in Des Moines County, with almost 56 percent of the county designated as prime farmland.

2.5 Geology

IAAAP is in the Dissected Till Plain section of the Central Lowland Physiographic Province of the Southern Iowa Drift Plain Landform Region. The facility is underlain by a sequence of unconsolidated glacial deposits of Pleistocene age (collectively known as overburden) overlying sedimentary bedrock units.

The overburden deposits near IAAAP include alluvium, loess, and glacial drift (including glacial till). The alluvium is composed of alluvial sediment (medium-to-fine-grained sandy silt with varying proportions of gravel) that was deposited in the stream valleys via water flow. Within the IAAAP, alluvium is typically present only near creeks, the Skunk River, and associated tributaries.

Loess, identified as the Peoria Loess near IAAAP, is windblown material composed principally of silt with small amounts of sand and clay and is the basis for the development of fertile soil. The loess was deposited during interglacial periods over the glacial drift. It is found throughout the state, including the plant. The glacial drift consists primarily of silty clay and clayey silt with thin sand seams and lenses and are assigned to the Kellersville Till Member (Illinoian Age) of the Glasford Formation of southeastern Iowa. Figure 2-4 presents a conceptual stratigraphic column for Iowa.

The glacial till extends to depths more than 100 feet below ground surface (bgs) in portions of the northern half of IAAAP, but it is thin or absent locally in deeper stream valleys in the south around Mathes Lake and in the northeast. In general, the glacial till is thicker in the upper reaches, especially in the Brush Creek watershed, and thins to the middle reaches. The till remains relatively constant in thickness in the Long Creek and Spring Creek watersheds.

The bedrock underlying IAAAP consists of a sequence of limestones interbedded with varying thicknesses of shales and sandstones ranging in age from Cambrian to Mississippian. The uppermost rock units within the area are the Warsaw Shale, the Keokuk Limestone, and the Burlington Limestone. There are two basic formations of importance at the facility, which are the uppermost rock units within the area, the Keokuk Limestone and Burlington Limestone of the Osage Series (Mississippian).

Geologic information collected at the individual IAAAP sites is summarized in Section 4. Conceptual cross sections were developed using soil boring log information across the facility. Figures 2-5, 2-6, and 2-7 are simplified geologic cross sections showing the distribution of the geologic layers at IAAAP.

2.6 Hydrogeology and Aquifer Properties

Des Moines County has four principal aquifers: the surficial (overburden) aquifer and the bedrock aquifers of Mississippian, Devonian, and Cambro-Ordovician units. The aquifers of concern for this RI at the IAAAP are the overburden aquifer and the youngest bedrock (Mississippian) aquifer. Figure 2-8 summarizes the hydrogeologic units in Des Moines Iowa. Site-specific discussions of the hydrogeologic aquifers, including depths to groundwater and localized flow patterns, are summarized in Section 4.

Consistent with regional hydrogeologic maps (Coble 1971), the overburden aquifer is composed predominantly of the unconsolidated glacial drift (Kellersville Till) in the upland, northern portion of the IAAAP and of the alluvium within the lower creek and river valleys in the southern portion of the IAAAP (Figure 2-9). The overburden aquifer typically does not include the loess; however, groundwater may exist at the loess–till geologic contact. In these cases, water migrates vertically through the loess. Upon reaching the till, it may “spread” out horizontally within the loess layer, because the permeability of the till is typically much lower than that of the loess. Therefore, vertical flow into the glacial till is restricted. This may also create perched water conditions. Because of the general low permeability of the glacial till, it may act like a confining layer within the surficial aquifer (IDNR, 2003). However, because the till includes beds of sand and gravel, more-permeable zones can be found within the aquifer. These sand beds, which are the result of episodes of meltwater during the glacial periods, are generally thin and discontinuous lenses. In contrast, in areas where the overburden aquifer exists primarily within the alluvium, the aquifer may yield moderate or high volumes of water. These aquifers are generally confined to stream valleys. Groundwater flow direction in the overburden aquifer typically mimics surface topography, with flow in southeasterly or southwesterly toward Brush Creek, Long Creek, Spring Creek, and the Skunk River (Figure 2-2).

Groundwater flow within the bedrock aquifers occurs primarily within secondary permeability zones, including fractures, joints, and bedding planes. Overall flow direction is to the south and east toward the Skunk and Mississippi Rivers, when not intercepted by incised surface drainages (Figure 2-3). The bedrock aquifers are separated by aquicludes, which are low-permeability geologic units that act as confining units and restrict groundwater flow between the aquifers. The Devonian and Cambro-Ordovician bedrock aquifers formations form the principal water-bearing zone near the IAAAP and occur at a depth of approximately 1,500 feet bgs (JAYCOR 1996). Water in these aquifers is reported to be highly mineralized and objectionably hard and contains high amounts of total dissolved solids.

Aquifer hydraulic conductivity (slug) testing has been performed at over 100 wells at the IAAAP, as part of previous investigations conducted between 1981 and 2003. Previous investigations at the individual IAAAP sites are summarized in Section 4. For wells screened in till and till combinations (such as fill and till, loess and till, or alluvium and till), hydraulic conductivity values ranged from 0.00035 foot/day to 4.3 feet/day, with an average of 0.64 foot/day. The higher range of values is indicative of wells screened within sandier layers whereas the lower range of value is indicative of wells screened predominantly within clay. For wells screened in bedrock and bedrock combinations (bedrock and till and bedrock and till/glacial outwash), hydraulic conductivity values ranged from 0.00015 foot/day to 51 feet/day, with an average of 2.3 feet/day. Slug test results are generally considered to represent an order-of-magnitude level of precision and accuracy in estimating horizontal hydraulic conductivity.

In areas where the overburden aquifer exists primarily within the glacial till, the aquifer typically has a very low yield (less than 10 gallons per minute; Figure 2-8). In comparison, aquifer yields within alluvium aquifers may yield 25 to 100 gallons per minute.

2.7 Ecology

Wildlife found in available habitats at IAAAP includes a large white-tail deer population, fox, gray squirrel, raccoon, woodchuck, coyote, eastern cottontail rabbit, mouse, mole, pocket gopher, beaver, muskrat, badger, opossum, and mink. To effectively manage the overpopulation of deer, limited recreational hunting has been allowed onsite. Recreational trapping of fur-bearing mammals is also allowed during limited times of the year (USACE, 2019).

Numerous bird species inhabit or migrate through the IAAAP. Some of the most common species include the American robin, northern cardinal, blue jay, red-headed woodpecker, common crow, common grackle, mourning dove, red-winged blackbird, chipping sparrow, eastern meadowlark, American goldfinch, and turkey. The red-headed woodpecker is protected under the Migratory Bird Treaty Act of 1918 (16 U.S. Code 703-712), which is administered by the U.S. Fish and Wildlife Service. Red-tailed hawks are the most common raptor species present, but bald eagles have been observed flying over the IAAAP or feeding on the fish they catch in Mathes Lake (H&S Environmental, 2016).

The U.S. Fish and Wildlife Service provided maintenance stocking of walleye and striped bass hybrids in Mathes Lake to predate on the abundant gizzard shad (*Dorosoma cepedianum*). Channel catfish are generally stocked in new impoundments or to supplement natural reproduction. Some natural channel catfish reproduction in Mathes Lake has been noted (H&S Environmental, 2016).

Federally listed threatened or endangered species that have been recorded on the IAAAP property include the Indiana bat (*Myotis sodalis*) and the northern long-eared bat (*Myotis septentrionalis*). The northern long-eared bat is listed as threatened throughout the State of Iowa (USFWS, 2018a). The Indiana bat is listed as endangered in a number of counties in Iowa including Des Moines. Based on information presented by the U.S. Fish and Wildlife Service (USFWS) (USFWS, 2018b), these species are fairly similar in ecology and life history. For example, USFWS (USFWS, 2018b) notes that “the northern long-eared bat and Indiana bat are both temperate, insectivorous, migratory bats that hibernate in mines and caves in the winter and spend summers in wooded areas.” Both species typically hibernate mid-fall through mid-spring each year. Suitable summer habitats for both species include a wide variety of forested/wooded habitats where they roost, forage, and travel. Some adjacent and interspersed non-forested habitats such as emergent wetlands and adjacent edges of agricultural fields, old fields, and pastures could occur in the forested habitats. The main habitat difference between the two bats appears to be that northern long-eared bats are typically associated with upland forests with generally more canopy cover than Indiana bats. They prefer upland, mature forests (Caceres and Pybus, 1998) with occasional foraging over forest clearings, water, and along roads (Jong, 1985). However, most foraging occurs on forested hillsides and ridges, rather than along riparian areas preferred by the Indiana bat (Brack and Whitaker, 2001; LaVal et al., 1977).

In 1999, a National Wetlands Inventory was conducted on the installation by the U.S. Fish and Wildlife Service. Based on the inventory, IAAAP contains 113.2 acres of wetland. Forested wetlands are the dominant type, representing about 50 percent of the installation's wetlands. The next most common type is unconsolidated bottoms ("ponds"), which comprise about 24 percent of the wetlands. IAAAP contains 57.3 miles of linear wetlands including rivers and streams (3.1 miles of wetlands and 54.2 miles of rivers and streams). Wetland acreages are as follows: Emergent Wetland—14.7 acres; Scrub/Shrub Wetland (Broadleaved Deciduous)—10.8 acres; Forested Wetland—60.2 acres (Temporarily Flooded—56.5 acres and Seasonally Flooded—3.7 acres); and Unconsolidated Bottom—27.5 acres (H&S Environmental, 2016).

2.8 Land and Resource Use

The current mission of the IAAAP is to load, assemble, and pack ammunition items. Public access to the installation is restricted by perimeter fencing and the IAAAP installation security staff. Approximately 8,000 acres of the IAAAP are leased for agricultural use, 7,500 acres are forested, and the remaining areas are used for administrative and industrial operations (USACE, 2016). Recreational facilities are located on the IAAAP property and in the area immediately surrounding the IAAAP. Hunting and fishing are regulated at the IAAAP using permits. There is also a boat ramp on the eastern shore of Mathes Lake. Currently, portions of Mathes Lake are used for recreational purposes by employees and the public.

Future residential use is not anticipated for IAAAP. The anticipated future land use at the IAAAP is commercial, industrial, agricultural, and recreational (USACE and Dawson, 2021). The final *Explanation of Significant Differences for the Records of Decision Soils Operable Unit 1 (OU-1)* (Leidos, 2018) establishes the requirements for land use controls (LUCs) for OU-1 areas and the excavation areas associated with the non-time-critical sump removal actions. LUCs will include (Leidos 2018):

> prohibitions on land use (e.g., through incorporation of a formal institutional control) to maintain commercial/industrial (i.e., nonresidential), to prohibit residential land use, and to prohibit the development and use of the property for elementary and secondary schools, childcare facilities and playgrounds.

Per the Record of Decision (ROD) for OU-5 (CB&I, 2014), LUCs have also been established as the remedy for Military Munitions Response Program areas. The LUCs for OU-5 consist of access restrictions (such as fencing and signage).

The land surrounding the IAAAP is characterized as rural and is expected to remain rural (USACE, 2016). The largest population centers are the towns of Burlington, West Burlington, Middletown, and Danville (U.S. Census Bureau, 2010). Near OU-3, the land use is predominantly rural, residential, and agricultural, and used mostly for corn and soybean production (USACE, 2016). Some of the farmland is reclaimed floodplain, meaning it has been elevated with drain tiles to control the water table. Some of the floodplain is owned by a commercial sand and gravel quarry which has recently expanded their land holdings into the contaminant plume extent. Other than the extension westward of the quarry, no significant change in future land use is known or anticipated (USACE, 2016). In 1994, all residences south of the IAAAP, east of an unnamed tributary of Skunk River that flows from the Line 3A area, and west of Spring Creek were offered connection to the Rathbun public water supply. Most of the residences were connected to the Rathbun public water supply as authorized by the 1993 Action Memorandum (Department of the Army, 1993); however, some residences declined or did not respond to the Army's 1993 offer. Groundwater is used for residential potable supply except where connections to the Rathbun Regional Water Supply have been made. Groundwater in this off-facility area is addressed under the OU-3 remedy.

Since 1977, IAAAP has received potable drinking water on a fee basis from the Burlington Regional Water Works in the town of Burlington. Burlington's water source is the Mississippi River. The

Burlington Regional Water Works pumps water from their treatment plant to the City of Burlington's distribution center. Groundwater use on the installation has been discontinued, and known production wells have been closed, including four deep groundwater wells that were closed in the early to mid-1990s. There are two exceptions: F-Yard Well #500-165-6, where groundwater from the IAAAP is used in cyclic heating of poured ammunition rounds, and D-Yard Well #500-165-5, from which groundwater supplies the restroom at Yard D (Busard, pers. comm., 2019).

SECTION 3

RI Field Investigation Activities

This section describes the methodology of the field investigation activities conducted as part of the current RI at IAAAP for the sites included in this report. Field activities were performed at the EDA from 2018 through 2020 to address data gaps identified in the final UFP-QAPP, which hindered completion of the RI at these IAAAP sites. Fieldwork was completed in accordance with the final site-specific worksheets of the UFP-QAPP (CH2M, 2018a). Previous investigations for these IAAAP sites are described in Section 5.

The field activities conducted during this RI consisted of the following activities:

- Site preparation/mobilization.
- Utility clearance.
- Monitoring well installation and development.
- Groundwater and surface water sampling.
- Surveying.
- Decontamination.
- Waste management.
- Data management.

Samples collected during the RI field investigation were submitted to preapproved, offsite laboratories (Test America Laboratory in Arvada, Colorado; Savanna, Georgia; and St. Louis, Missouri; and Eurofins Laboratory in Lancaster, Pennsylvania).

This section provides an overview of the RI field activities. Section 5 provides specific investigation objectives and RI field investigations for individual IAAAP sites. Appendix B contains laboratory reports and the data quality evaluation. Appendix C contains the field documentation, Appendix D contains the waste management documentation, and Appendix E contains the survey data as applicable to the 2018–2020 RI monitoring well installation activities.

3.1 Site Preparation/Mobilization

3.1.1 Permits/Base Access

Fieldwork was coordinated with USACE and appropriate installation points of contact, including AO, the onsite contractor at the IAAAP. Work clearances and permits were obtained for all field activities. Laydown areas for equipment storage and staging were made available and determined through coordination with AO points of contact.

CH2M team field personnel obtained construction identification badges from AO Security prior to conducting field activities. CH2M team personnel obtained camera passes from AO Security. Well keys were signed out and returned daily at AO Security.

3.1.2 Biological/Ecological Survey

Prior to intrusive activities and any vegetation removal, an IDNR-approved biologist walked each of these sites to inspect and eliminate potential impacts to federally protected species, including the Indiana bat (*Myotis sodalist).* All intrusive work was coordinated with base Natural Resources manager and conducted within permitted months.

3.1.3 Vegetation Removal

Because many of the proposed sampling locations were in heavily vegetated areas, clearance was required to allow site access. Vegetation clearance was performed by Allworth Contracting (Allworth) or PARS using both mechanical and manual methods. Allworth or PARS field personnel cut vegetation consisting of grass, shrubs, brush, and small trees. The paths and work areas were maintained, as needed, by PARS for the duration of the investigation.

3.1.4 Utility Survey

Prior to the start of any intrusive work, CH2M identified and marked sampling locations and coordinated activities with the AO representatives. In addition, the Underground Detective was contracted by CH2M to perform third-party utility location activities at offsite locations. AO completed third-party utility clearance prior to all intrusive activities at the IAAAP.

In addition to the utility location activities, all proposed intrusive drilling locations were cleared to check for buried utilities using hand augers to a depth of at least 5 feet bgs.

3.2 RI Investigation Methods

Additional field work was conducted at the IAAAP sites below to resolve data gaps needed to complete the RI, per the final UFP-QAPP. The following field activities were conducted in 2018 through 2020:

- EBPs—monitoring well installation, well development, groundwater sampling, water level gauging, surveying, and waste management
- WBPA—monitoring well installation, well development, groundwater sampling, surface water sampling, staff gauge installation, water level gauging, surveying, and waste management
- NBP—monitoring well installation, well development, groundwater sampling, water level gauging, surveying, and waste management
- NBPLF—monitoring well installation, well development, groundwater sampling, water level gauging, surveying, and waste management
- FTP—groundwater sampling, water level gauging, surveying, and waste management

This section describes the field methods that were implemented. Site-specific details, including the selected sampling or well installation methods, are provided in Section 5.

3.2.1 Permanent Monitoring Well Installation

The permanent monitoring wells were installed in accordance with the final UFP-QAPP (CH2M, 2017a) using direct-push technology (DPT), hollow-stem auger, downhole hammer, or rotosonic drilling methods. During drilling, continuous soil samples were collected to log the soil lithology. Grain size, color, moisture content, consistency, and other observations such as evidence of contamination were recorded. Appendix C contains the soil boring logs.

New monitoring wells were constructed with a 2-inch-inside-diameter Schedule 40 PVC screen and a riser with a 0.010-inch slot size screen. A silica sand filter pack was placed around the annular space of the well screen from the bottom of the boring and well screen to a depth of about 2 feet above the top of the screen. A bentonite layer roughly 2 feet thick was placed at the top of the sand pack. After the bentonite was allowed to hydrate, a cement-bentonite grout was placed in the remaining annular space to the surface. The monitoring wells were completed flush to ground surface with a traffic-rated, watertight, steel vault and locking watertight cap. Appendix C contains the well construction diagrams.

See Section 5 for details on permanent monitoring wells installed at the IAAAP sites in this RI report.

3.2.2 Monitoring Well Development

New monitoring wells were developed at least 24 hours after installation was completed to remove fine-grained sediment generated during construction. Monitoring wells were developed by a combination of bailing, surging, and pumping. Well development continued until water quality parameter readings stabilized with three consecutive readings, in accordance with the final UFP-QAPP (CH2M, 2017a), unless otherwise mentioned in Section 5. Well development information, including water quality data and the volume of groundwater removed, was recorded on a well development log or in the field logbook. Appendix C contains the well development logs. See Section 5 for details on well development activities at the IAAAP sites in this RI report.

3.2.3 Water Level Survey

Manual groundwater elevation measurements were obtained from monitoring wells using an electronic water level meter with 0.01-foot graduations. The depth to water in each well was measured from a designated point on top of the well casing.

3.2.4 Groundwater Sampling

Groundwater samples were collected from DPT locations, temporary monitoring wells, and permanent monitoring wells at the IAAAP sites. Groundwater samples were collected using a peristaltic pump and disposable tubing from DPT locations or wells with depths to water of less than 30 feet bgs. In wells with depths to water greater than 30 feet, a submersible bladder pump was used to collect samples. Groundwater quality parameters (pH, specific conductance, turbidity, dissolved oxygen, temperature, salinity, and oxidation-reduction potential) were collected using a water quality meter and were recorded on purge logs. Groundwater quality parameters were allowed to stabilize for three consecutive readings before each well was sampled.

Groundwater samples were collected in laboratory-prepared sampling containers that were pre-preserved based on the analytical method and submitted to Test America or Eurofins. See Section 5 for details on monitoring well sampling at the IAAAP sites in this RI report.

3.2.5 Surface Water Gauging

New staff gauges were installed at Spring Creek to evaluate surface water–groundwater interaction. The staff gauges were installed at accessible locations of Spring Creek. Gauge stations consisted of a metered vertical panel and were fixed in place by driving rods into the subsurface. Once installed, staff gauges were surveyed in place. See Section 5.2 for details on surface water gauging at the IAAAP sites in this RI report.

3.2.6 Surface Water Sampling

Surface water samples were collected from Spring Creek and onsite tributaries. Surface water samples were collected by direct grab or via a sample transfer device (for example, a peristaltic pump), depending on location accessibility. Surface water samples were collected in laboratory-prepared sampling containers that were pre-preserved based on the analytical method and submitted to Test America or Eurofins. See Section 5.2 for details on surface water sampling at the IAAAP sites in this RI report.

3.2.7 Surveying

New monitoring wells and staff gauges were surveyed by State of Iowa–licensed professional surveyor Bruner, Cooper & Zuck. The surveyors set up horizontal and vertical control for the site. Accuracy of the control was held to the Third Order Class I as outlined in the *Geospatial Positioning Accuracy Standards,* *Part 4: Standards for Architecture, Engineering, Constructions (A/E/C) and Facility Management* (Federal Geographic Data Committee, 2002).

The surveyor provided coordinates of the points *x*, *y*, and *z* to the nearest 0.01 foot. Horizontal coordinates conformed to North American Datum (NAD) 83 and the vertical elevations were referenced to National Geodetic Vertical Datum (NAVD) 88 with ties to the Iowa State Plane Coordinate System. Appendix E contains the survey report.

Soil borings and temporary well locations were surveyed using a global positioning system (GPS). Locations of new soil borings were determined using real-time kinematic GPS coordinates, with GPS accuracy dependent on site-specific conditions such as canopy cover.

3.2.8 Decontamination and Waste Management

Decontamination and waste management activities were conducted in accordance with the final *Basewide Environmental and Waste Management Plan* (CH2M, 2018b). Investigation-derived waste (IDW) generated during the RI included drill cuttings from the soil borings and monitoring well installations, well development and purge water, and decontamination fluids used to decontaminate nondisposable sampling equipment. New, United Nations–approved 55-gallon steel drums were used to contain waste generated during the field activities.

Groundwater generated during well development was temporarily stored in labeled drums or portable tanks. Groundwater was disposed of at the onsite Inert Disposal Area groundwater treatment facility with approval from IAAAP.

Downhole and nondisposable sampling equipment was decontaminated immediately after each use. Water generated during decontamination of sampling equipment was collected and transferred to an onsite groundwater treatment facility. Reusable heavy equipment, such as drilling rods and augers, was decontaminated before and in between the collection of each sample using a high-pressure steam cleaner with potable-grade water. Pressure washing was conducted at temporary decontamination pads. Decontamination fluids were captured and containerized for disposal at the onsite groundwater treatment facility.

IDW was temporarily stored at the installation approved staging location and properly labeled. The soil drums were sampled by CH2M for waste characterization. Based on the analytical results, IDW was classified as nonhazardous and disposed of at the Des Moines County Regional Landfill in West Burlington, Iowa, and the Clean Harbors facility in Cincinnati, Ohio. Appendix D contains the final executed manifests.

3.3 Data Management and Evaluation

3.3.1 Data Tracking

Data management and tracking was conducted from the time of field collection to receipt of validated electronic analytical results. Field samples and their corresponding analytical tests were recorded on the chain-of-custody forms submitted with the samples to the laboratory. Chain-of-custody entries were checked against the site-specific project instructions and work plans to verify that the designated field samples had been collected and submitted for the appropriate analysis. Upon receipt of the samples by the laboratories, a comparison to the field information was conducted to verify that each sample was analyzed for the correct parameters, and appropriate quality assurance/quality control samples were collected.

3.3.2 Data Quality Assessment

CH2M performed a data review and verification as described in the UFP-QAPP (CH2M, 2017a). The data quality of analytical results from the samples collected during the field investigation was assessed.

Analytical data were validated as Stage 2B level evaluations. Qualifier flags were applied to the data to reflect data usability limitations. The data review and verification efforts are documented in the data quality evaluation report (Appendix B).

The results are usable for project objectives, unless otherwise detailed in Appendix B. Based on the verification effort, the data appear to accurately represent the conditions of the environmental media analyzed at the time of collection, as detailed in Section 5. The analytical techniques were properly performed and documented, and the laboratory procedures applicable to each method were followed and documented. Standard industry laboratory methods were used to analyze the data as prescribed in the approved UFP-QAPP (CH2M, 2017a). Summary tables of the reported data, including both detections and nondetects, are included in Section 5.

3.4 Deviations

Deviations from the final UFP-QAPP and site-specific worksheets are site-dependent and are therefore discussed in Section 5.

SECTION 4

Approach for RI Data Evaluation

Data from previous investigations were used to assess the nature and extent of contamination and evaluate for potential site-related impacts. This section describes the approaches used for the RI data evaluation for the IAAAP sites.

4.1 Nature and Extent Approach

4.1.1 Site Characterization Project Action Limits

In accordance with the final UFP-QAPP (CH2M, 2017a), screening values used for site characterization differ from those used to select chemicals of potential concern (COPCs) in the risk assessments. The site characterization screening levels (SLs) were used to assess the distribution and nature and extent of chemicals whereas more conservative screening values were used for risk assessment (see Section 4.3.2). The final selected project action limit objectives are summarized in Appendix F.

For site characterization, chemical concentrations were compared with project action limits (PALs) listed in the final UFP-QAPP (CH2M, 2017). The PALs considered for the IAAAP sites included in this report are summarized below:

- Soil based on human health:
  - USEPA Regional Screening Level (RSL) for residential soil (hazard quotient [HQ] = 1), May 2023 (USEPA, 2023a).
- Soil based on ecological goals:
  - USEPA Region 4 Ecological Screening Values (EVS) (USEPA, 2018b).
  - USEPA Region 5 Ecological Screening Levels for Soil (USEPA, 2003a).
- Groundwater based on human health (maximum contaminant level, or MCL, to be used; if no MCL is available, the greater of the Health Advisory Level and the RSL):
  - Federal MCL, March 2018 (USEPA, 2018c).
  - USEPA RSL for tap water (HQ = 1), May 2023 (USEPA, 2023a).
  - Health Advisory Level (lifetime), March 2018 (USEPA, 2018c).
- Sediment based on human health:
  - HHRA sediment RSL (HQ=1) for a recreational scenario (USEPA, 2023a).
- Sediment based on ecological goals (listed in the order of selection):
  - USEPA Region 4 Ecological Screening Values (ESVs) (USEPA, 2018b).
  - USEPA Region 5 Ecological Screening Levels for Sediment, August 2003 (USEPA, 2003a).
  - USEPA Region 3 Biological Technical Assistance Group for Freshwater Sediment, August 2006 (USEPA, 2006).
- Surface water based on human health (lowest of the two objectives):
  - Iowa Ambient Water Quality Criteria Standard, Fish Consumption, Iowa Administrative Code, Chapter 61 (2019).

  - HHRA Surface Water RSL (HQ=1) for a recreational scenario (USEPA, 2023a).
- Surface water based on ecological goals (listed in the order of selection):
  - Iowa Ambient Water Quality Criteria Chronic, IAC Chapter 61 (2019).
  - USEPA National Recommended Water Quality Criteria—Aquatic Life Criteria Table (USEPA, 2020a).
  - USEPA Region 4 ESVs (USEPA, 2018b).
  - USEPA Region 5 Ecological Screening Levels for Surface Water, August 2003 (USEPA, 2003a).
  - USEPA Region 3 Biological Technical Assistance Group for Freshwater, July 2006 (USEPA, 2006).

4.1.2 Background Threshold Values

USEPA's (2002) *Role of Background in the CERCLA Cleanup Program* guidance states that risk management and remedial actions for CERCLA sites should account for the influence of natural and anthropogenic background conditions, and that cleanup goals for chemicals of concern from an identified CERCLA release should not be set below their corresponding background concentrations. Background concentrations for natural and anthropogenic chemicals are also used for comparison to site data to support the identifications of a site-related release.

Accordingly, analytical data were compared to the background values calculated for the IAAAP to assess whether the detected concentrations were consistent with the background concentrations for metals; site-specific discussions are included in Section 5. Background threshold values (BTVs) were calculated for groundwater at IAAAP and documented in the final *Evaluation of Background Concentrations of Metals in Groundwater* (CH2M, 2020a). BTVs were also developed for sediment and surface water specific to three of the watersheds at IAAAP: Brush Creek, Long Creek, and Spring Creek. BTV calculations are documented in the draft *Evaluation of Background Concentrations of Metals in Sediment and Surface Water* (CH2M, 2020b). Background values were established for soil as part of the *Reevaluation of Background Concentrations of Metals in Soil* (Jacobs, 2022).

BTVs are presented in the site-specific screening tables in Section 5 of this report.

4.2 Chemical Fate and Transport Overview

The properties of chemicals and the environment are used to understand and predict chemical fate and transport. An understanding of the fate and transport is part of the overall assessment of the potential for a chemical to cause an adverse human health or environmental effect. This section provides an overview of the fate and transport properties of chemicals previously identified as COPCs at IAAAP. Site-specific discussions are included in Section 5.

Based on previous investigations at IAAAP, the main COPCs that occur at the IAAAP sites are in five contaminant classes: explosives, volatile organic compounds (VOCs), polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs), and metals. Semivolatile organic compounds (SVOCs) other than the PAHs were rarely considered to be site-related, and pesticides were detected infrequently.

4.2.1 Chemical Mobility and Persistence

The mobility and persistence of potential contaminants are determined by their physical, chemical, and biological interaction with the environment. Mobility is the potential for a chemical to migrate from a site, and persistence is a measure of how long a chemical will remain in the environment. Some of the mechanisms controlling mobility and persistence are described as follows:

- *Volatilization* occurs when a compound transfers from the aqueous phase to the gas phase. Measures of a chemical's tendency to volatilize from water and soil moisture include its vapor pressure and Henry's law constant (K_h). Volatilization tends to occur more readily from surface water, sediment, or shallow soil than from deeper soil or groundwater.
- *Sorption* occurs when a constituent adheres to and becomes associated with solid particles. The soil and sediment media likely to sorb chemicals are clays and organic matter. The conventional measure of sorption is the distribution coefficient (K_d). The K_d for organic chemicals is typically the product of the soil organic carbon partition coefficient (K_{oc}) of the chemical and the fraction of organic carbon in the soil. Metals sorption potential is a complex function of pH, organic content, oxide coatings, and other factors; therefore, K_d is not easily estimated by methods other than site-specific testing (USEPA 1996). Generally, metals adsorption increases with pH and they most often sorb to clay minerals, organic matter, and iron and manganese oxyhydroxides.
- *Solubility* is a measure of the degree to which a constituent will dissolve in water. Highly soluble chemicals are more likely to be leached from soil by precipitation or runoff that infiltrates into the subsurface.
- *Degradation* is the deterioration or destruction of a chemical, either biologically (through biodegradation) or abiotically (through such processes as abiotic reduction, hydrolysis, and photolysis). Biodegradation of chemicals by microbial organisms occurs through metabolic or enzymatic processes. The rate of degradation is dependent on the chemical, biological, and physical conditions of the medium in which the contaminant is located.
- *Transformation* occurs when the valence state of metals is increased (oxidation) or decreased (reduction). It can be caused by changes in oxidation potential or pH and by microbial or nonmicrobial (abiotic) processes. Transformation may have a significant effect on the mobility of a metal, either increasing or decreasing it.

Physical and chemical properties for the primary COPCs identified at the IAAAP are summarized in Table 4.2-1; information provided in Table 4.2-1 supports fate and transport discussions in the site-specific sections of this report as well as risk assessment calculations, which utilize values presented on the USEPA risk assessment website (USEPA, 2022a).

4.2.1.1 Explosives

The explosives at the IAAAP are characterized by limited volatility, moderate solubility, and low sorption potential (U.S. National Library of Medicine, 2015). The explosives are subject to biodegradation; however, degradation occurs under varying mechanisms. RDX, which is the most prevalent explosive at the IAAAP, most favorably degrades under anaerobic conditions (Pennington et al., 1999) in which it is reductively degraded to hexahydro-1-nitroso-3,5-dinitro-1,3,5-triazine (MNX), then hexahydro-1,3-dinitroso-5-nitro-1,3,5-triazine (DNX), and subsequently to hexahydro1,3,5-trinitroso-1,3,5-triazine (TNX). Other intermediates may also be formed, such as formaldehyde, methanol, hydrazine, 1,1-dimethylhydrazine, and 1,2-dimethylhydrazine (Battelle, 2015). RDX is also subject to abiotic degradation and can be transformed to methylene dinitramine. However, it will not be completely degraded to carbon dioxide via this mechanism alone.

In comparison, TNT can be aerobically biodegraded, reduced by hydrogen under anaerobic conditions, or degraded by biotic cometabolism. TNT can be also degraded abiotically by hydrolysis or reduced by iron. Amino-dinitrotoluenes (DNTs) are intermediate transformation products of TNT reduction under oxic or anoxic conditions (Battelle, 2015). 4-Amino-2,6-dinitrotoluene is also a daughter product of the abiotic transformation of TNT.

HMX can be biodegraded under anaerobic conditions, most favorably under sulfate-reducing conditions. It will degrade to methane and chloroform under anaerobic conditions when a mixed microbial consortium is present (Battelle, 2015).

2,4-DNT and 2,6-DNT can be biodegraded under aerobic and anaerobic conditions. However, 2,4-DNT can be resistant to aerobic biodegradation under certain conditions (ATSDR, 2013). The DNTs can be used as the sole energy source or degraded via cometabolism with ethanol, methanol, and acetic acid. Potential aerobic degradation products include amino-nitrotoluene isomers, carbon dioxide, nitrite, or nitrate. Nitrite can inhibit further 2,6-DNT degradation. Anaerobic degradation can also result in diaminotoluenes. 2,4-DNT and 2,6-DNT are subject to abiotic degradation via photolysis, ozonation and chlorination, or oxidation by strong oxidants. The presence of the amino-DNT isomers (such as, 4-amino-2,6-DNT) in groundwater may be byproducts of anaerobic biodegradation of 2,6-DNT. These amino-DNTs can be further degraded to nitrotoluenes (McFarlan, 1998).

4.2.1.2 Volatile Organic Compounds

VOCs detected at the IAAAP include chlorinated volatile organic compounds (CVOCs); benzene, toluene, ethylbenzene, and xylenes (BTEX); and Freon 113. The K_h values for VOCs indicate that they are expected to volatilize quickly from surficial soil and surface water (U.S. National Library of Medicine 2015). The VOCs are also characterized by relatively high solubilities and low sorption potential. CVOCs are subject to degradation by biological and abiotic mechanisms. Under anaerobic conditions, biodegradation typically occurs by reductive dechlorination, a naturally occurring process in which chlorine atoms on a parent CVOC molecule are sequentially replaced with hydrogen. Some CVOCs can be aerobically biodegraded via aerobic cometabolism to carbon dioxide. They are also subject to abiotic degradation, mainly mediated by iron-bearing minerals in the subsurface under reducing conditions. Aromatic VOCs, such as BTEX, can be biodegraded in oxidation-reduction reactions, in which the contaminant is used as the electron donor by the microorganism. Biodegradation will occur when enough electron acceptors, electron donors, and nutrients are available in groundwater. Freon 113 has been observed to undergo biodegradation under anaerobic and aerobic conditions; however, the degradation rate may be slow, and the contaminant may be persistent (U.S. National Library of Medicine, 2015).

4.2.1.3 Polycyclic Aromatic Hydrocarbons

PAHs are a group of organic compounds consisting of two or more rings comprising six carbon atoms. The number of rings significantly affects the properties of the molecule. High-molecular-weight PAHs, such as benzo(a)pyrene, generally have limited volatility, very low water solubility, and high sorption potential. On the contrary, low-molecular-weight PAHs, such as naphthalene, have moderate volatility, moderate water solubility, and moderate sorption potential (U.S. National Library of Medicine 2015). Therefore, naphthalene has greater mobility than high-molecular-weight PAHs.

PAHs can be biodegraded under aerobic and anaerobic conditions (U.S. National Library of Medicine, 2015). However, aerobic biodegradation occurs at a much faster rate. The principal mechanism for aerobic metabolism is the initial oxidation of the benzene ring by the action of oxygenases. Nevertheless, PAHs sorbed to organic matter may be less available for biodegradation. In general, high-molecular-weight PAHs are more recalcitrant than low-molecular-weight PAHs and as a result have longer half-lives.

4.2.1.4 Pentachlorophenol

Pentachlorophenol (PCP) has been observed to degrade anaerobically by reductive dechlorination. To complete anaerobic degradation, each chlorine molecule acts as an electron acceptor and is replaced by hydrogen, producing first tetrachlorophenol, then trichlorophenol, dichlorophenol, chlorophenol, and finally phenol before the aromatic ring is broken relatively late in the process. Possible intermediate breakdown products include three isomers of tetrachlorophenol, five isomers of trichlorophenol, six isomers of dichlorophenol, and three isomers of chlorophenol. The pathway that is followed at a specific site appears to depend on the type of microorganism present in the system (Mahaffey, 1997). For anaerobic degradation of PCP to occur, highly anaerobic conditions must exist in the aquifer; dissolved oxygen levels below 0.5 mg/L are necessary in the groundwater.

In the aerobic degradation of PCP, the phenol ring is broken during an early stage of the process and complete mineralization to carbon dioxide, water and chloride occurs much more quickly than through the anaerobic pathway. Initial intermediate products that form prior to breaking the phenol ring may include tetrachloroatechol, tetrachlorohydroquinone, tetrachlorobenzoquinone, trichlorohydroxylbenzoquinone, tert-butylhydroquinone, dichlorohydroquinone, and chlorohydroquinone (Mahaffey, 1997). For aerobic oxidation to occur, a dissolved oxygen concentration in the groundwater of at least 2 mg/L is typically required.

4.2.1.5 Polychlorinated Biphenyls

The most common PCBs detected at IAAAP were Aroclor 1254 and Aroclor 1260. These chemicals are relatively immobile in the environment and are persistent. PCBs have moderate volatility, high sorption potential, and low water solubility. Higher-weight PCBs (such as Aroclors 1254 and 1260) are resistant to aerobic biodegradation (U.S. National Library of Medicine, 2015). Anaerobic reductive dechlorination of these PCBs can occur but may require enhancement to achieve effective degradation rates. These PCBs do not significantly degrade abiotically in the environment.

4.2.1.6 Metals

Due to the complexity of metals and their variable forms in the environment, predicting their chemical mobility and persistence can be difficult. Typically, they are not volatile under normal temperature and pressure conditions. Their sorption potential is a complex function of pH, organic content, oxide coatings, and other factors; therefore, K_d is not easily estimated by methods other than site-specific testing (USEPA, 1996). Generally, metal adsorption increases with pH. Metals most often sorb to clay minerals, organic matter, and iron and manganese oxyhydroxides. Metals may be sorbed on the surface of the soil or fixed to the interior of the soil, where they are unavailable for release to groundwater. After available sorption sites are filled, most metals are incorporated into the structures of major mineral precipitates as coprecipitates (ERG, 2005).

The solubilities of metals are also dependent on several factors. In general, solubility is highly dependent on the oxidation state of the metal (USEPA, 2007). The solubility of cations (positively charged ions) decreases as pH increases. Some cations may complex with oxygen and hydroxide, forming insoluble oxyhydroxides, or with phosphate, sulfate, and carbonate, forming insoluble mineral precipitates. Metal sulfide complexes, which form in reducing environments, are extremely insoluble and tend to reduce the total metals concentrations (ERG, 2005).

The solid forms of iron (iron hydroxides) and manganese (manganese oxides) are present in the natural soil matrix. If insufficient amounts of oxygen and nitrate are present in the subsurface, then iron hydroxides and manganese oxides will be used as electron acceptors during metabolic activity and dissolve under reducing conditions into soluble forms. Sulfides present in groundwater can also result in the dissolution of iron hydroxides. Several metals (such as arsenic) tend to sorb to these iron hydroxides and manganese oxides. If these iron and manganese compounds are dissolved, the metals that are bound to these hydroxides and oxides (such as chromium and arsenic) will also be released. Iron also becomes more soluble as pH drops below 7 (ERG, 2005).

Subsurface conditions are likely to become more reduced in areas that have substantial carbon available. Several metabolic processes can use naturally occurring organic carbon or anthropogenic organic compound contamination as an electron donor or electron acceptor. Metal concentrations, in particular iron and manganese and those metals that tend to desorb from iron and manganese oxyhydroxides when they are reduced to their more soluble forms, are also frequently higher in areas of organic contamination (such as explosives or VOC plumes) because of the reducing conditions that are created during biodegradation of these chemicals (USEPA, 2017a).

4.2.2 Chemical Transport

Contamination at the IAAAP is attributed primarily to historical load, assembly, and pack operations for ammunitions. In particular, there appear to be several contaminant plumes emanating from wastewater treatment buildings along the production lines. Sources of contamination at the individual sites are discussed in Section 5.

Figure 2-9 depicts the CSM for the IAAAP and supports the fate and transport discussion. It qualitatively combines and interprets physical characteristics and the nature and extent of contamination. Primary migration pathways for potential contaminants at IAAAP include the following:

- Volatilization of contaminants in surface soil and surface water.
- Volatilization of contaminants in subsurface soil and shallow groundwater due to construction/ excavation activities.
- Volatilization of contaminants into unsaturated zone soil gas at the water table interface.
- Transport of contaminants sorbed to soil via historical wastewater discharge, stormwater runoff/ erosion, and wind erosion to drainage ditches.
- Leaching of contaminants in soil to groundwater.
- Advection of dissolved contaminants with groundwater flow.
- Discharge of contaminants in groundwater through sediment and into surface water.
- Surface water transport of chemicals within drainage ditches and creeks.

Migration pathways for potential contaminants at IAAAP are further discussed below in the context of their location (i.e., unsaturated zone, surface water, sediment, stormwater, and saturated zone migrations).

4.2.2.1 Unsaturated Zone Migration

Contaminants released to the ground surface migrated through the unsaturated zone, as controlled by the chemical and physical differences between the contaminants and the surrounding media, gravity, and pressure (head). Once in the unsaturated zone, contaminants may have sorbed to soil or organic matter, become trapped in residual pore spaces, or continued to leach to the saturated zone. Although the explosives and VOCs have lower K_{oc} values, the contaminants could still sorb to soil in areas of higher clay or total organic carbon content. The high-molecular-weight PAHs and PCBs have a strong tendency for sorption. Once in the soil, contaminants can enter the gas phase through volatilization of soil contaminants. Higher soil temperatures in the upper few feet of soil occur during the summer and can lead to increased volatilization. Constituents sorbed or complexed to surface soil may be transported to sediment via surface water runoff.

The IAAAP includes areas that are covered by asphalt, concrete, buildings, and heavy vegetation. In portions of the site that are covered by impermeable asphalt or concrete, infiltration into the subsurface and potential leaching of contaminants in the unsaturated zone is significantly limited. In those areas of the site that are vegetated, there is little to no restriction for infiltration. Explosives, VOCs, and low-molecular-weight PAHs have leached from the unsaturated zone to groundwater. In contrast, due to the high sorption potential and low water solubility of high-molecular-weight PAHs and PCBs, these contaminants are largely immobile in the unsaturated zone and unlikely to appreciably leach to groundwater. Based on their moderate volatility, PCBs may evaporate into soil gas and then into the atmosphere; however, volatilization would be limited due to adsorption to soil.

Most metals at the IAAAP are naturally occurring in the environment and not associated with a CERCLA release. In southeast Iowa, iron and manganese have been identified as being problems and are frequently detected at concentrations above recommended screening values (Coble, 1971). The mobility of metals in the unsaturated zone is highly dependent on the subsurface conditions. Surface soil and shallow subsurface soil (within the top 2 feet of the ground surface) exist under more oxidizing conditions due to the proximity to outdoor air; therefore, aluminum, manganese, and iron will tend to be in their immobile forms of aluminum hydroxides, manganese oxides, and iron hydroxides. In oxidizing environments, arsenic and chromium are typically present in forms that are more mobile (ERG, 2005). However, these metals, along with lead, thallium, and zinc, will potentially sorb or complex with clays, organic material, iron hydroxides, or manganese oxides, limiting their mobility.

4.2.2.2 Surface Water, Sediment, and Stormwater Runoff Migration

Intermittent stormwater runoff can transport contaminants in surface soil and deposit them potentially in creeks at the IAAAP. Transport occurs when contaminants are either dissolved in the stormwater/ runoff or sorbed to particulate matter small enough to be carried by the intermittent stormwater flow. Runoff may be locally limited by vegetation, where present.

Once the contaminants are transported to the surface water features, they can be further carried with surface water flow. Heavier particles will tend to deposit to the bottom as sediment, unless the surface water flow is strong. Volatilization of volatile contaminants would be rapid from shallow surface water, particularly if there is shallow turbulent flow, such as that which occurs in small creeks.

Within the creeks, explosives and VOCs would be expected to dissolve in surface water. The VOCs would volatilize quickly, but the explosives would be more likely to stay dissolved in water. Any high-molecular-weight PAHs and PCBs would preferentially stay sorbed to sediment and be migrated only via particle entrainment. Low-molecular-weight PAHs and PCBs may moderately volatilize into the atmosphere, although volatilization would be limited due to adsorption to sediment. In contrast, high-molecular-weight PAHs are unlikely to evaporate. Unlike surface soil, sediment is often subject to more reducing conditions due to the presence of organic matter, which may facilitate biological redox reactions.

4.2.2.3 Saturated Zone Migration

Contaminants have entered groundwater at the IAAAP primarily by leaching through unsaturated zone soil. However, sumps at the IAAAP, which were located below the water table, may have also contributed to groundwater contamination. Contaminants in the overburden aquifer have been transported from the source release areas through advection and dispersion. Advection is the primary transport mechanism and includes the transport of dissolved contaminants by the bulk motion of flowing groundwater. Dispersion is the spreading of dissolved contaminants from the path they would be expected to follow during advection due to the spatial variation in aquifer permeability, fluid mixing, and molecular diffusion. Contaminants in groundwater may volatilize into unsaturated zone soil gas at the water table interface.

Groundwater flow in the overburden aquifer is influenced by the hydrologic watersheds and flows generally southeasterly or southwesterly toward Brush Creek, Long Creek, Spring Creek, and the Skunk River. Groundwater contaminants near these waterbodies may discharge through sediment and into surface water in portions of the creeks that are considered gaining. Due to differences in the permeability, groundwater discharge is greater in the alluvium than in the glacial till. However, when surface water levels are high, during periods of high precipitation, surface water may serve as a recharge point for groundwater. Groundwater contaminants may also discharge into localized drainage ditches; however, this is less likely since the drainages are often dry at the IAAAP. Groundwater discharge to surface water bodies is indicated by upward vertical gradients. Overburden aquifer groundwater can also flow downwards toward the bedrock aquifer. This would be indicated by downward vertical gradients. However, contaminant migration between the aquifers would be limited due to physical differences between the surficial (overburden) geology and the primary bedrock matrix and pressure (head). Groundwater in bedrock flows primarily through secondary porosity features, like fractures. Where the bedrock crops close to the surface, groundwater flow is also influenced by the watersheds.

Contaminants typically will not move as rapidly as groundwater because of retardation, or the adsorption of the contaminant to the solid media. Retardation can be a significant factor for groundwater COPCs within the overburden aquifer, which is composed primarily of clays and silts. Retardation will not be important where sand lenses are present from the glacial meltwater.

As previously mentioned, organic contamination in groundwater is composed primarily of explosives and VOCs. The explosives have moderate solubilities, but relatively low sorption potential. Therefore, they are subject to moderate migration, which may vary based on the specific constituent. The VOCs in groundwater may volatilize into soil gas overlying the water table. These constituents also have high to moderate aqueous solubilities and have the potential to migrate once dissolved in groundwater. All of the organic groundwater COPCs are subject to biodegradation.

Transport and partitioning of metals in water is dependent on the oxidation state of the metal and on interactions with the other materials present. Under reducing conditions, iron and manganese would be expected to be transformed into more soluble forms. Any metals (such as arsenic and zinc) which may be naturally bound to iron hydroxides and manganese oxides can also become more mobile. Arsenic can also coprecipitate in groundwater.

4.3 Risk Assessment Approach

Risk assessments were conducted to assess the potential for unacceptable risk or hazards to human health and adverse effects to the environment posed by site-related contamination. The media evaluated for the areas included in this report are detailed in Section 5 and summarized below.

- Groundwater: EBPs, WBPA, NBPs, NBPLF, and FTP.
- Surface Water: WBPA.
- Sediment: WBPA.

Risk assessments were not conducted for soil within the EDA, as this media has been addressed under OU-1.

4.3.1 Human Health Risk

This section provides the general method used in the HHRAs. As noted in Section 1.2.4, site-specific discussions for the IAAAP sites included in this report are provided in Section 5. The results of the site-specific HHRAs are also included in Section 5 to provide a more comprehensive CSM for each of these IAAAP areas. The supporting risk tables are provided in Appendix A.

The approach and assumptions used in the HHRA are consistent with those provided in the final UFP-QAPP (CH2M, 2017a), except for some deviations that were agreed to during meetings or correspondence with USACE and USEPA following approval of the final UFP-QAPP, and are consistent with those provided in the interim HHRAs for Line 2, Line 6, and Building 600-86 (CH2M, 2019, 2020c; Leidos, 2020). While none of these sites are included in this report, the IAAAP project team agreed that these interim deliverables would serve as examples for the HHRA approach at all of the IAAAP sites, including the sites included in this OU-10 RI report. The purpose of these interim deliverables, as stated for Superfund Sites in the USEPA's *Risk Assessment Guidance for Superfund (RAGS*), is to present the planning documents, specifically RAGS Part D Tables. The interim HHRAs presented the exposure scenarios, analytical data, data groupings, results of the screening for COPCs, exposure point concentrations (EPCs) in exposure media, exposure factor values for receptors, and toxicity values for the COPCs.

HHRAs were completed for all of the IAAAP sites included in this RI report. The primary objective of each HHRA was to evaluate and document the potential risks and hazards to human health associated with potential current and future exposures to chemicals at these IAAAP sites in the absence of any remedial action. The HHRAs were completed in accordance with the USEPA's *RAGS, Volume I, Human Health Evaluation Manual* [HHEM]*,* Parts A, D, E, and F (USEPA, 1989, 2001a, 2004, 2009); HHEM *Supplemental Guidance: Update of Standard Default Exposure Factors* (USEPA, 2014a); and *Risk Assessment Handbook, Volume I: Human Health Evaluation* (USACE, 1999). If there are inconsistencies between the methods presented in the USACE and USEPA guidance documents, preference is given to USEPA guidance in the risk assessment.

The HHRAs consist of a four-step evaluation process:

1. **Data evaluation and identification of COPCs.** Identification of the appropriate HHRA data set and selection of the COPCs, including concentration contributions from both site-related COPCs and naturally occurring chemicals. COPCs identified in this step are the focus of the subsequent steps of the HHRA.
2. **Exposure assessment.** Identification of potential pathways of human exposure, characterization of the potentially exposed populations, and estimation of the magnitude, frequency, and duration of exposures.
3. **Toxicity assessment.** Assessment of the potential adverse effects of the COPCs (site-related COPCs and naturally occurring chemicals) and compilation of the toxicity values used for developing numerical risk and hazard estimates.
4. **Risk characterization.** Integration of the results of the exposure and toxicity assessments to develop numerical estimates of potential health risks and hazards, including a discussion of sources of uncertainty associated with the data, method, and exposure and toxicity values used in the HHRA. For each IAAAP site, the risk characterization is a four-step process that (1) presents estimates of potential risks and hazards that include contributions from site-related COPCs and naturally occurring chemicals; (2) presents risks and hazards due to background and identifies naturally occurring chemicals; (3) presents risks and hazards from site-related COPCs; and (4) through weight-of-evidence evaluations, identifies final COCs, if any, that warrant further evaluation in a Feasibility Study. The identification of no COCs indicates the conditions for NFA are met on an HHRA basis.

4.3.1.1 Potential Receptors

The following potential current and future human receptors were considered for the IAAAP sites included in this RI report, and the exposure scenarios applicable to each site are discussed in the HHRAs, as provided in Section 5.

Potential Current Exposure Scenarios

- **Hunters/Recreators.** Hunters/recreators could contact sediment and surface water in permanent water bodies. To effectively manage the overpopulation of deer, limited recreational hunting is permitted at some areas within IAAAP (Appendix A-1). Recreational trapping of fur-bearing mammals is also allowed during limited times of the year. For an individual site, potential exposures to hunters were evaluated only if hunting/trapping is permitted at the site, as shown in Appendix A-1, Attachment 1. For the IAAAP sites included in this RI report, surface water and sediment exposures for the entire EDA were evaluated with the WBPA.
- **Site Workers.** Site workers could be exposed to COPCs in indoor air (which may be impacted by VOCs migrating from groundwater). Potential indoor air exposures to current site workers were only considered at sites with currently active buildings. Although the NBPLF itself is inactive, there is an actively occupied building (Building BG-199-4) at this IAAAP area. A current site worker scenario was only evaluated for indoor air risks and hazards if the estimated risks and hazards for a hypothetical

residential scenario exceeded acceptable risk and hazard levels and COCs were identified for a residential scenario.

Potential Future Exposure Scenarios

- **Site Workers.** Future site workers could contact groundwater if groundwater is used as a future drinking water source at the IAAAP sites. Additionally, future site workers could contact COPCs in indoor air (that may be impacted by VOCs migrating from groundwater) in existing buildings or in potential future buildings if a site is redeveloped. However, potential exposures and risks and hazards to site workers were estimated in the HHRAs only if the estimated risks and hazards for a hypothetical residential scenario—potable use or vapor intrusion (VI)—exceeded acceptable risk and hazards levels and COCs were identified for a residential scenario.
- **Construction/Utility Workers.** Future construction/utility workers could contact shallow groundwater while replacing a culvert. For groundwater, potential exposures and risks and hazards to construction/utility workers are estimated in the HHRAs only if the estimated risks and hazards for a hypothetical residential scenario (potable use) exceed acceptable risk and hazards levels and COCs were identified for a residential scenario. Based on conversations with staff at IAAAP, replacing culverts is infrequent (i.e., every few years over a duration of approximately 2 weeks), and contact with shallow groundwater is expected to be minimal (i.e., less than 1 hour per day during culvert replacement). Additionally, repairs to sewer or water lines are very infrequent, are completed in 1 or 2 days and are too insignificant to evaluate in the HHRAs.
- **Hypothetical Residents.** Future hypothetical residents (young child ages 0 to 6 years and adult) may contact groundwater based on potential future use as a potable water source at the IAAAP sites. Additionally, future residents could contact COPCs in indoor air (that may be impacted by VOCs migrating from groundwater) if future residences are constructed at the IAAAP areas included in this report.

Although the current and expected future Land Use of the IAAAP is Commercial/Industrial, hypothetical future residents are being evaluated for exposures to groundwater at the OU-10 areas as a means for determining if the conditions meet the criteria for NFA or UU/UE. Although none of the areas at the IAAAP are anticipated to undergo residential redevelopment, the hypothetical residential scenario allows for evaluation of the least restrictive land use scenario. According to "Land Use in the CERCLA Remedy Selection Process" (USEPA, 1995), the presence of contaminants in media at concentrations protective of residential exposures allow for unrestricted land use and negates the need for further action for a human health risk scenario.

The human health conceptual exposure model (CEM) for each IAAAP site in this report is discussed in Section 5. The media and potential exposure scenarios evaluated for each site are provided in Table 4.3-1.

4.3.1.2 Data Evaluation and Identification of Chemicals of Potential Concern

Data Evaluation

The data evaluation step involves gathering and reviewing available site data and identifying a data set of acceptable quality for the HHRAs. Soil and groundwater samples from historical investigations and from the recent investigations conducted between 2018 and 2020, as documented in the final UFP-QAPP (CH2M, 2017a), were included in the HHRAs. The historical data were evaluated to determine whether they were likely to still be representative of current site conditions. The data sets included in the HHRAs for each site are discussed in Section 5.

The data were evaluated using the following procedures:

- A value qualified as "B" or "J" was treated as a detected value.

- "U" qualified results were treated as nondetected values.
- "UJ" qualified results were treated as nondetected values, with the reporting limit being estimated.
- "R" (rejected) qualified results were not included in the HHRA data sets.
- For sample locations where a duplicate sample or a split sample was collected, the highest detected concentration among the original, duplicate, or split samples was used when a chemical was detected in any sample. If all results were nondetect, the lowest reported detection limit (DL) (that is, RL) was used.

Groundwater Data Groupings

For a future potable use scenario, groundwater samples collected from the overburden and bedrock aquifers within a site boundary were combined (if bedrock groundwater was potentially impacted and sampled), and groundwater was assumed to be potable at all depths. USEPA guidance (USEPA, 2014b) recommends that only "total" concentrations be used to evaluate a potable use scenario if both "total" and "dissolved" metals data are available in the groundwater data set; therefore, only "total" metals data were presented in the risk assessment tables and text of the HHRAs.

For the VI pathway, groundwater samples collected from the overburden and bedrock aquifers within a site boundary were combined. The groundwater samples were not collected at multilevel wells; therefore, a separate data grouping was not used to evaluate the VI pathway (i.e., the same data grouping was used for potable use and the VI pathway scenarios).

Surface Water/Sediment Data Groupings

Surface water and sediment samples were collected from perennial surface water features and were used to evaluate hunting and other recreational activities if permitted at these sites.

Selection of Site-related Chemicals of Potential Concern and Naturally Occurring Chemicals

The COPCs (site-related COPCs or naturally occurring chemicals) are those chemicals that, based on screening, have the potential to cause adverse human health effects if receptors contact site media. Chemicals considered to be essential nutrients (calcium, magnesium, potassium, and sodium) were not selected as COPCs in the HHRAs because they are toxic only at high doses and high concentrations of essential nutrients are not present at the sites.

Chemicals that were 100 percent not detected in a data grouping were not identified as COPCs for that data grouping; however, an evaluation of the 100 percent nondetected chemicals within a medium was included in the Uncertainty Analysis sections in the HHRAs. DLs and RLs (if available) for chemicals that were 100 percent nondetected in a medium were compared against SLs. Chemicals with exceedances are discussed regarding the age of data, the potential to be related to former site activities, and the potential to be associated with laboratory contamination. The detection of a chemical within that medium on an IAAAP facility-wide basis at a frequency greater than 5 percent (based on historical non-FUSRAP facility data) was also considered when determining the significance of the DL or RL above its SL and its potential to be site-related. The results of the evaluation for the nondetected chemicals are provided in Section 5.

Screening Levels

The SLs used in the HHRA for each exposure medium are described below. A detected chemical was retained as a COPC (site-related COPC or naturally occurring chemical) in an exposure medium if the maximum detected concentration exceeded the corresponding SL for that exposure medium.

- **Groundwater (Potable Use).** Concentrations detected in groundwater for a potable use scenario were compared to USEPA's tap water RSLs (USEPA, 2023a). For lead, the groundwater concentrations were compared to the USEPA's Action Level of 15 µg/L. USEPA's MCLs (USEPA, 2009) were included in the groundwater screening tables for comparison purposes (i.e., as an applicable or relevant and appropriate requirement) but were not used to select COPCs. If an MCL was not available, the Lifetime Health Advisory (USEPA, 2018c) was provided for comparison purposes. The MCLs are enforceable standards and are used as a line of evidence in the risk characterization to determine final COCs in the HHRAs.

- **Groundwater Vapor Intrusion.** Concentrations detected in groundwater for the VI pathway were compared to USEPA's groundwater vapor intrusion screening levels (VISLs), calculated using the VISL Calculator (USEPA, 2023b). The default groundwater to indoor air attenuation factor of 0.001 and IAAAP-specific average groundwater temperature of 13 degrees Celsius (based on groundwater samples collected from 2000 to 2018) were used in the VISL calculations. The VISL Calculator input and output is provided in Appendix A-1, Attachment 3. Chemicals detected in groundwater that were not considered to be sufficiently volatile were excluded as COPCs for the VI pathway.[2]
- **Surface Water/Sediment.** Concentrations detected in surface water and sediment were compared to SLs calculated for a recreational scenario (i.e., adult and adolescent hunters) using the RSL online calculator. An exposure frequency of 26 days/year and an exposure time of 2 hours/event was used; the body weight used for the adolescent hunter is 44.3 kilograms (kg). The RSL calculator input and output are provided in Appendix A-1, Attachment 4, Table 1 and Table 2, respectively; Table 1 presents the exposure factors for receptors.

The RSLs and VISLs were based on a target excess lifetime cancer risk (ELCR) of 1×10^{-6} and a noncancer HQ of 0.1. The HQ of 0.1 was used as the target hazard level for noncarcinogenic health endpoints to account for the potential presence of multiple chemicals affecting the same target organ. For those chemicals with a carcinogenic-based RSL and a noncarcinogenic-based RSL, the lowest value was selected as the final RSL for that chemical. If the maximum detected concentration of a constituent exceeded its respective SL, it was retained as a COPC (site-related COPC or naturally occurring chemical) in the HHRA.

The BTVs are provided in the COPC screening tables for comparison purposes and were not used as a basis for selecting or eliminating COPCs. Instead, the BTVs are used to determine which chemicals are naturally occurring at the sites, as provided in the nature and extent evaluations in Section 5. The results of the background comparisons are used in the risk characterization process to distinguish between naturally occurring chemicals and site-related COPCs. For sites where no known or suspected release of metals has occurred, if the site maximum detected concentration (MDC) is less than the upper tolerance limit for the BTV, the metal is considered naturally occurring. If the site MDC is greater than the background upper tolerance limit, the metal is considered site-related.

4.3.1.3 Exposure Assessment

An exposure assessment is used to evaluate potential exposures to site media by the human receptors identified for current and anticipated future land uses at the IAAAP sites. The exposure assessment identifies potential human receptors, potential exposure pathways, exposure factor values, and EPCs.

Exposure Pathways Quantified in the HHRA

An exposure pathway can be described as the physical course that a chemical takes from the point of release (or source) to a receptor. To be complete, an exposure pathway must have all the following components:

- A source (such as constituent residues in an environmental medium).

[2] Chemicals with a Henry's Law Constant value greater than or equal to 1×10^{-5} atm-m^3/mole or a vapor pressure greater than or equal to 1 mm Hg are considered by USEPA to be sufficiently volatile.

- A mechanism for chemical release and migration (such as groundwater infiltration).
- An environmental transport medium (such as groundwater).
- A point of potential human contact (exposure point, such as tap water).
- A route of intake (such as ingestion, dermal contact, or inhalation).

In the absence of any one of these components, an exposure pathway is considered incomplete, and, by definition, there is no risk or hazard.

Groundwater is not currently being used as a potable water source and there are no plans to use groundwater for potable purposes in the future; however, based on applicable CERCLA policy and guidance, groundwater at the IAAAP sites is classified as Class IIB, a potential source of drinking water (USEPA, 1989). Therefore, the evaluation of future residential exposures to groundwater has been included in the HHRA. It is assumed that future hypothetical residents could use groundwater as a potable water source. Ingestion, dermal contact, and inhalation exposures to COPCs in groundwater were estimated in the HHRA based on a potable use scenario. Additionally, hypothetical future residents could also inhale volatile groundwater chemicals (if present in groundwater) that have migrated to indoor air from VI.

The potential exposure pathways quantified for each site are discussed in the HHRAs, as provided in Section 5.

Exposure Point Concentrations

The upper confidence limit (UCL) of the mean concentration was calculated for each COPC where at least eight samples were available and at least four detected concentrations were observed. The UCLs were estimated following the most recent parametric (distributional) and nonparametric USEPA recommendations in ProUCL (Version 5.1.002) (USEPA, 2016). ProUCL provides approaches for calculating UCLs particularly when nondetected concentrations are present. These approaches consider a large variety of input including the perceived distribution of the detected results (if no perceived distribution is acceptable, nonparametric alternatives are provided), sample size, variability, and skewness. The arithmetic mean concentrations provided in the RAGS Part D Table 3 series were calculated using only detected results. For exposure media where lead was identified as a COPC, the arithmetic mean concentration was used as the EPC.

If a groundwater plume[3] was identified for a site, the groundwater EPCs were calculated based on the data collected in the core of the plume, in accordance with USEPA's *Determining Groundwater Exposure Point Concentrations, Supplemental Guidance* (USEPA, 2014b). When eight samples and at least four detected concentrations were available from the core of the plume, the EPC was calculated as the UCL on the mean; otherwise, the maximum detected concentration was used as the EPC. If no plume was identified for a site, all samples in the groundwater data set were used to calculate the EPCs for the COPCs in groundwater. EPCs are also calculated as the UCL on the mean when eight samples and at least four detected concentrations were available for the site groundwater; otherwise, the maximum detected concentration was used as the EPC.

Exposure Factors and Chemical Intake Calculations

A reasonable maximum exposure scenario was quantified for potential residential receptors under a hypothetical future land use scenario (USEPA, 1989). USEPA defines the reasonable maximum exposure as the highest exposure that could reasonably be expected to occur for a given exposure pathway at a site and is intended to account for both uncertainty in the chemical concentration and for variability in

[3] A plume is interpreted as a three-dimensional, dynamic (i.e., may vary temporally), potentially irregular distribution of contaminants dissolved or suspended in groundwater (USEPA, 2014b).

the exposure parameters (such as exposure frequency or averaging time). If available, site-specific values are applied as equation inputs. In the absence of site-specific values, default values are obtained or calculated based on values provided in current USEPA guidance such as the HHEM *Supplemental Guidance: Update of Standard Default Exposure Factors* (USEPA, 2014a). The exposure factors used in the HHRAs are provided in the RAGS Part D Table 4 series for each site (Appendix A).

The exposure factors are used as equation inputs for calculating chemical intakes. A chemical intake occurs when a chemical is taken into the body via a route of exposure (i.e., ingestion, dermal contact, or inhalation) and is subsequently absorbed into the bloodstream. Depending on the exposure duration, exposures are characterized as chronic or subchronic. Chemical intakes via all routes are calculated in accordance with the USACE's *Risk Assessment Handbook* (USACE, 1999) and USEPA's RAGS Part A (USEPA, 1989). Additionally, dermally absorbed doses are calculated for dermal exposures in accordance with USEPA's RAGS Part E (USEPA, 2004), and air exposure concentrations (ECs) are calculated for inhalation exposures in accordance with USEPA's RAGS Part F (USEPA, 2009).

Calculations of chemical intakes are provided in the RAGS Part D Table 7 series for each area-pathway-receptor combination (Appendix A).

For hypothetical future residents, noncarcinogenic exposures are calculated separately for child (0 to 6 years) and adult residents as daily intakes. For carcinogenic exposures, daily intake rates are age-adjusted based on child (0 to 6 years) and adult parameters (e.g., intake rates, exposure duration, and body weights) and averaged over a lifetime (i.e., 70 years).

Approach for Mutagenic Exposures

For COPCs with a mutagenic mode of action (MMOA) for carcinogenesis, in the absence of age-specific toxicity data, the risk for exposures that occur at early life stages was estimated by applying the default age-dependent adjustment factors (ADAFs) to address the potential for increased carcinogenic potency associated with exposure during early life (less than 16 years of age). Consistent with the *Cancer Guidelines* (USEPA, 2005a) and *Supplemental Guidance* (USEPA, 2005b), the estimated risks for specific age groups were calculated using the following ADAFs: less than 2 years (ADAF of 10), 2 to less than 16 years (ADAF of 3), and greater than 16 years (ADAF of 1).

Approach for Lead Exposures

The potential risks associated with lead exposures for a hypothetical residential scenario were addressed using the Integrated Exposure Uptake Biokinetic (IEUBK) Model and USEPA's recommended input parameter values (USEPA, 1994, 2010, 2017b, 2017c, 2021). The IEUBK Model was designed to provide predictions of the probability of elevated blood lead levels (BLLs) for children. This model addresses three components of environmental risk assessments—the multimedia nature of exposures to lead, lead pharmacokinetics, and significant variability in exposure and risk—through estimation of probability distributions of BLLs for children exposed to similar environmental concentrations. The measured site concentration, calculated as the arithmetic mean, was used for the exposure medium where lead was identified as a COPC, and the default ECs embedded in the IEUBK Model were used for exposure media where lead is not a COPC.

In 2012, the Advisory Committee on Childhood Lead Poisoning Prevention (ACCLPP) conducted a critical review of available lead toxicity studies and reported that the overall weight of evidence substantiates that neurocognitive decrements (as well as other adverse systemic effects, such as cardiovascular, immunological, and endocrine effects) can occur in children, even when BLLs are less than 10 micrograms per deciliter (µg/dL) (ACCLPP, 2012). Based on the conclusion that BLLs below 10 µg/dL can harm children, the ACCLPP and Centers for Disease Control and Prevention (CDC, 2007) have recommended that a revised reference value of 5 µg/dL of blood lead be used to identify children with elevated BLLs. Therefore, the blood lead reference level of 10 µg/dL was replaced with the reference level of 5 µg/dL in the IEUBK Model, in accordance with the final UFP-QAPP (CH2M, 2017a). Additionally, the default maternal blood lead concentration at childbirth was updated from 1 µg/dL to 0.6 µg/dL in the IEUBK Model, as recommended by USEPA (2017b). In accordance with recent USEPA guidance (USEPA, 2017c, 2021), the default age range for children was changed from 0 to 84 months to 12 to 72 months because soil and dust ingestion rates are generally lower for children aged 0 to 12 and 72 to 84 months.

4.3.1.4 Toxicity Assessment

The toxicity assessment describes the relationship between the magnitude of exposure to a constituent and the possible severity of adverse effects and weighs the quality of available toxicological evidence. Where possible, this assessment provides a numerical estimate of the increased likelihood and/or severity of adverse effects associated with chemical exposure (USEPA, 1989).

The toxicity values for carcinogenicity (oral cancer slope factors [CSFs] and inhalation unit risks [IURs]), as well as for noncarcinogenic effects (oral reference doses [RfDs] and inhalation reference concentrations [RfCs]), that are used in the HHRAs were obtained from the USEPA standard hierarchy of toxicity value sources (USEPA, 2003b), as follows:

- Tier 1 Source—Integrated Risk Information System (USEPA, 2023c).
- Tier 2 Source—USEPA Provisional Peer-Reviewed Toxicity Values.
- Tier 3 Sources—Other peer-reviewed federal and state toxicity values, as cited in the RSL table (USEPA, 2023a).[4]
  - Agency for Toxic Substances and Disease Registry (ATSDR, 2020).
  - California Environmental Protection Agency toxicity database (Cal EPA, 2020).
  - USEPA's Health Effects Assessment Summary Tables (USEPA, 1997a).

The noncarcinogenic toxicity values and carcinogenic toxicity values used in the HHRAs are provided in the RAGS Part D Table 5 series and 6 series, respectively, for each site (Appendix A).

Noncarcinogenic Toxicity Values

Noncarcinogenic hazards typically are quantified by comparing intakes to oral RfDs and inhalation RfCs. The RfD is a health-based dose, expressed as a constituent intake rate in units of milligrams of chemical per kilogram body weight per day (mg/kg-day). The RfC is an allowable, health-based concentration of a constituent in air expressed in units of milligram per cubic meter (mg/m^3). Both the RfD and RfC are based on the assumption that thresholds exist for certain toxic effects, such as liver or kidney damage, but may not exist for other toxic effects such as carcinogenicity. In general, the RfD and RfC are estimates (with uncertainty spanning perhaps an order of magnitude) of daily exposures to the human population (including sensitive subgroups) that are likely to be without an appreciable risk of deleterious effects during a lifetime of exposure (USEPA, 1989).

Noncarcinogenic toxicity values are available for both chronic and subchronic exposures. As a guideline, chronic RfDs and RfCs are used to evaluate the potential noncarcinogenic effects associated with exposure periods greater than 7 years (approximately 10 percent of a human lifetime). Chronic RfDs and RfCs are applied in the hazard calculations for the following IAAAP receptor scenarios: site worker, hunter/recreator, and hypothetical residents (child and adult). Subchronic oral RfDs and inhalation RfCs are developed specifically to be protective for short-term exposures. As a guideline, USEPA recommends that subchronic toxicity values be used to evaluate potential noncarcinogenic effects of exposure periods between 2 weeks and 7 years. For the IAAAP sites included in this RI report, subchronic RfDs and

[4] The Tier 3 toxicity value sources used in the HHRAs were identified as appropriate by the USEPA and are consistent with the USEPA's RSL User's Guide (May 2023). Priority was given to toxicity value sources that are most current, peer reviewed, transparent, and publicly available.

RfCs are applied in the hazard calculations to only the construction/utility worker scenario, for which a combined exposure frequency and duration is assumed to be less than 1 year.

Carcinogenic Toxicity Values

Potential carcinogenic risks were quantified using oral CSFs and IURs. The CSF is defined as a plausible upper-bound estimate of the probability of developing cancer per unit intake of a constituent over a lifetime (USEPA, 1989). In general, CSFs can be derived from the results of chronic animal bioassays, human epidemiological studies, or both. CSFs, which are expressed in units of kilogram body weight per day per milligram chemical (kg-day/mg or $[\text{mg/kg-day}]^{-1}$), were used to estimate upper-bound lifetime statistical probabilities of current and future receptors developing cancer because of exposure to COPCs in site media. The IUR is defined as the upper-bound ELCR estimated to result from continuous exposure to a chemical at a concentration of 1 $\mu g/m^3$ in air. IURs are expressed in units of cubic meter of air per micrograms of chemical ($m^3/\mu g$ or $[\mu g/m^3]^{-1}$).

Derivation of Dermal Toxicity Values

Oral RfDs and CSFs were converted to dermal RfDs and CSFs using an oral-to-dermal adjustment factor. The values used for this conversion were obtained from *RAGS Part E* Section 4.2 and Exhibit 4-1 (USEPA, 2004). Following USEPA's recommendation, such a conversion was performed only when a chemical has a gastrointestinal absorption factor of less than 50 percent. If a chemical-specific adjustment factor was not available, a default value of 100 percent was used.

If the gastrointestinal absorption factor was less than 50 percent, the dermal RfD was derived by multiplying the oral RfD by the gastrointestinal absorption factor as shown with the following equation:

$$RfD_d = RfD_o \times ABS_{GI}$$

where:

RfD_d	=	Dermal reference dose (mg/kg-day)
RfD_o	=	Oral reference dose (mg/kg-day)
ABS_{GI}	=	Fraction of constituent absorbed in the gastrointestinal tract (unitless)

The dermal CSF was derived by dividing the oral CSF by the gastrointestinal absorption factor as shown with the following equation:

$$CSF_d = \frac{CSF_o}{ABS_{GI}}$$

where:

CSF_d	=	Dermal cancer slope factor $(\text{mg/kg-day})^{-1}$
CSF_o	=	Oral cancer slope factor $(\text{mg/kg-day})^{-1}$
ABS_{GI}	=	Fraction of constituent absorbed in the gastrointestinal tract (unitless)

Special Considerations

The Integrated Risk Information System oral RfD for manganese (0.14 mg/kg-day) includes manganese from all sources, including diet (USEPA, 2023c). An oral RfD for nondiet exposures was calculated by subtracting the dietary contribution from the normal U.S. diet (an upper limit of 5 mg/day) and applying a modifying factor of 3 to address uncertainties associated with nonfood manganese exposure sources, resulting in an oral "nondiet" RfD of 0.024 mg/kg-day. This oral "nondiet" RfD was used to estimate potential noncarcinogenic HQs associated with exposures to manganese in groundwater at the OU-10 sites.

The oral RfD for vanadium (0.005 mg/kg-day) was derived from the oral RfD for vanadium pentoxide (0.009 mg/kg-day). The vanadium oral RfD was calculated by factoring out the molecular weight of the oxide ion. The two atoms of vanadium contribute 56 percent of the molecular weight for vanadium pentoxide. Therefore, the oral RfD for vanadium pentoxide was multiplied by 56 percent to calculate the oral RfD for vanadium (0.005 mg/kg-day). This calculated RfD was used to estimate potential noncarcinogenic HQs associated with exposures to vanadium in groundwater at the IAAAP sites.

The toxicity values for hexavalent chromium were used to estimate potential noncarcinogenic HQs and carcinogenic risks for total chromium due to the lack of speciated chromium data available for media at IAAAP sites. Hexavalent chromium is typically present as a fraction of the total chromium concentrations; therefore, using the hexavalent chromium toxicity values to evaluate total chromium detected in site media is a conservative approach.

Quantitative oral toxicity values are not available for lead; therefore, potential exposures to lead for a hypothetical residential scenario were addressed using USEPA's IEUBK model (USEPA, 2010) and USEPA's updated input parameter values, as discussed in Section 3.3.1.3.

4.3.1.5 Risk Characterization

Potential human health risks are discussed separately for noncarcinogenic and carcinogenic COPCs because of the different toxicological endpoints, relevant exposure durations, and methods used to estimate risk. The methodologies and equations used to estimate noncarcinogenic hazards and carcinogenic risks are discussed below.

Estimation of Noncarcinogenic Hazards

For the ingestion and dermal contact exposure routes, noncarcinogenic hazards were estimated by comparing the calculated intakes to RfDs. The calculated intake was divided by the RfD, as presented in the following equation. This ratio is referred to as the HQ:

$$HQ = {}^{Intake}\!/_{RfD}$$

where:

HQ	=	unitless hazard quotient
Intake	=	intake level (mg/kg-day)
RfD	=	reference dose (mg/kg-day)

Intake and RfD are expressed in the same units (mg/kg-day) and represent the same exposure period (i.e., chronic or subchronic). An HQ that exceeds 1 (i.e., intake exceeds the RfD) indicates that there is a potential for adverse health effects associated with exposure to that COPC for that specific exposure route.

Similarly, the HQ associated with the inhalation of a noncarcinogenic COPC is calculated as follows:

$$HQ = {}^{EC}\!/_{RfC}$$

where:

HQ	=	unitless hazard quotient
EC	=	air exposure concentration (mg/m^3)
RfC	=	reference concentration (mg/m^3)

An HQ that exceeds 1 (i.e., air EC exceeds the RfC) indicates that there is a potential for adverse health effects associated with exposure to that COPC for the inhalation exposure route.

To assess the potential for noncarcinogenic health effects posed by exposure to multiple COPCs and exposure routes, a hazard index (HI) approach was used (USEPA, 1989). This approach assumes that noncarcinogenic hazards associated with exposure to more than one COPC and exposure route are additive. Synergistic or antagonistic interactions among COPCs are not quantified. The HI may exceed 1 even if all the individual HQs are less than 1. The COPCs were separated by similar mechanisms of toxicity and toxicological effects and separate HIs were calculated for each specific target organ, target system, or critical effect on which the RfDs or RfCs are based.

Estimation of Carcinogenic Risks

The potential for carcinogenic effects due to exposure to site media was evaluated by estimating the ELCR. The ELCR is the incremental increase in the probability of developing cancer during one's lifetime above the background probability of developing cancer. The linear low-dose equations were used to estimate the incremental probability of an individual developing cancer over a lifetime because of exposure to potential carcinogens.

Potential ELCRs associated with ingestion and dermal exposure to individual carcinogens were calculated using CSFs and intake estimates. The equation used to estimate the potential ELCRs is as follows:

$$ELCR = Intake \times CSF$$

where:

ELCR	=	unitless excess lifetime cancer risk
Intake	=	intake level (mg/kg-day)
CSF	=	cancer slope factor $(\text{mg/kg-day})^{-1}$

Similarly, the ELCR associated with the inhalation of a carcinogenic COPC is calculated by multiplying the lifetime average EC by the IUR).

$$ELCR = EC \times IUR$$

where:

ELCR	=	unitless excess lifetime cancer risk
EC	=	air exposure concentration ($\mu g/m^3$)
IUR	=	inhalation unit risk $(\mu g/m^3)^{-1}$

The theoretical probability of developing cancer from exposure to two or more COPCs and by two or more exposure pathways was calculated by summing the ELCRs for each COPC.

Risk Characterization Process for IAAAP Sites Included in RI Report

This risk assessment document reflects certain procedural departures from the standard USEPA HHRA process that the Army routinely applies at its installations (USEPA, 1989). An example is the inclusion in the HHRA of onsite detected chemicals with concentrations that are either the same or less than those of their respective site-specific background concentrations (naturally occurring chemicals). Such an approach adds extraneous information into the HHRA process. The intent of COPC screening is to minimize the scope of risk assessments by eliminating chemicals that will have no bearing on risk and hazard outcomes, and per 40 Code of Federal Regulations 300.400(b)(1) CERCLA, background (naturally occurring) substances are not subject to remedial actions. The Army considers that initially computing risks and hazards for all detected chemicals only to secondarily recompute risks and hazards without the risks from the naturally occurring chemicals (background) is not useful and makes the risk assessment results confusing to the public. The knowledge of risks associated with naturally occurring chemicals does not contribute to the determination of remedial actions that may be required to address an impact from former DoD activities. Importantly, computing risks and hazards for chemicals without having first conducted background screening is not a conservative gesture. Groundwater background values were obtained from the technical memorandum *Evaluation of Background Concentrations of Metals in Groundwater, Iowa Army Ammunition Plant, Middletown, Iowa. Final* (CH2M, 2020a). This background comparison method is consistent with the UFP-QAPP (CH2M, 2017a, Worksheet #14). Although inconsistent with the process the Army uses for background in the HHRA for their installations, this method complies with the requests from the USEPA (USEPA, 2019) based on the OSWER 9285.6-07P guidance.

The risk characterization evaluations and results for the IAAAP sites included in this RI report were completed using a four-step process, as follows:

Step 1: Total Combined Risks and Hazards from Site-Related COPCs and Naturally Occurring Chemicals

Step 1 consists of calculation of receptor-specific ELCRs and HIs that include contributions from both site-related COPCs and naturally occurring chemicals. These total risk estimates are only provided for informational purposes per the request of the USEPA (USEPA, 2019). No decisions for future remedial actions are based on the total risk estimates. As stated in *Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA* (USEPA, 1988) and *RAGS Part A* (USEPA, 1989), the risk characterization should be conducted to determine the potential risks and hazards associated with site-related contamination. Some contaminants can be both naturally occurring and site-related. However, chemicals that are considered naturally occurring at a site, or consistent with background, will be treated as naturally occurring chemicals in the risk assessment. Naturally occurring chemicals (and the estimated risks and hazards associated with their concentrations) are not site-related contaminants. The ELCRs and HIs calculated in Step 1 are not used to determine final COCs for a site.

Step 2: Risk Characterization of Naturally Occurring Chemicals

Step 2 consists of calculation of receptor-specific ELCRs and HIs for naturally occurring chemicals. Naturally occurring chemicals were identified using the IAAAP-specific BTVs; the comparison of metals concentrations to BTVs is provided in the nature and extent discussions for each site in Section 5. Risks and hazards associated with naturally occurring chemicals are not used to determine if remedial actions are warranted and are not considered in the determination of final COCs because they are consistent with background levels and not site-related.

Step 3: Risk Characterization of Site-Related COPCs

Step 3 consists of calculation of receptor-specific ELCRs and HIs for site-related COPCs. Site-related COPCs from this step are retained for the fourth and final step of the risk characterization.

Step 4: Final COC Determination

In this final step of the risk characterization, all site-related COPCs are evaluated quantitatively and qualitatively to determine which are final COCs (and require remedial actions, such as a Feasibility Study); if no COCs are identified, the site qualifies for an NFA decision per the HHRA.

USEPA guidance generally considers an acceptable site ELCR range to be within 1 in 1,000,000 to 1 in 10,000 (1×10^{-6} to 1×10^{-4}). Generally, remedial actions are not warranted for site media with an ELCR of 1×10^{-4} or less, or an HI of 1 or less. Lead is typically identified as a COC if the predicted BLLs in more than 5 percent of the exposed population exceed the reference BLL of 10 µg/dL. As discussed in Section 4.3.1.3 and in accordance with the final UFP-QAPP (CH2M, 2017), a reference BLL of 5 µg/dL was used for the HHRAs.

The final COCs were identified for a site based on the ELCRs and HIs calculated for the site-related COPCs in step 3 of the risk characterization. If an ELCR of 1×10^{-4} was exceeded for a receptor group, the COPCs posing an individual ELCR greater than 1×10^{-6} were identified as COCs. When a target organ–specific HI exceeded 1 for a receptor group, the COPCs posing an individual HQ greater than 0.1 for that target organ were identified as COCs. Groundwater COPCs for potable use and trenching scenarios detected at concentrations less than or equal to their respective MCLs were excluded as final COCs. COPCs detected above their respective MCL were included as COCs per OSWER Directive 9283.1-33, if applicable. Additionally, some COPCs may be excluded as final COCs based on a weight-of-evidence approach, such as a comparison of concentrations and risks and hazards based on “dissolved” and “total” metals data and a comparison of recent versus historical site concentrations.

4.3.1.6 Uncertainty Analysis

The assumptions used in the HHRAs have inherent uncertainty. While it is possible that this leads to underestimates of potential risk and hazards, the use of upper-bound assumptions most likely results in conservative estimates of potential risks and hazards. A receptor group’s potential exposure and subsequent potential risk and hazards are influenced by the exposure scenario and dose/response and vary on a case-by-case basis. The general uncertainties associated with the HHRAs are provided in Table 4.3-2. Site-specific uncertainties associated with each HHRA are provided in Section 5.

Typically, the very first screen, applicable to all categories of chemicals (e.g., inorganic, anthropogenic, etc.) is for frequency of detection. In brief, chemicals that occur in 5 percent or less of samples for a given medium, are usually eliminated because it is evident up front, that these chemicals will play an insignificant role. In this risk assessment, no chemicals were screened out based on frequency of detection. The second screen is typically a background screen, and it would be for naturally occurring chemicals only (principally inorganic compounds, such as metals). Organic chemicals such as pesticides or solvents should not be present in site background, and if they are, an alternate site background location must be sought. In this screening, the maximum onsite metal detection is typically compared with a value that is twice the mean concentration for the metal in site background. Where the maximum onsite concentration is less than “the two-times-the-background-mean” concentration, the metal is typically removed from all other consideration in the HHRA. In these risk assessments, the background screen was not done before the risk-based screening. USEPA recommends a baseline risk assessment approach that retains chemicals that exceed risk-based screening concentrations. USEPA’s approach described in *Role of Background in the CERCLA Cleanup Program* (EPA, 2002) “involves addressing site-specific background issues at the end of the risk assessment, in the risk characterization.” The third screening task is risk-based screening and was completed for these sites. The maximum detected onsite concentration of a chemical was compared to their current USEPA RSL table (USEPA, 2023a), wherein the values reflect a cancer risk level of 1×10^{-6} (for carcinogens), and an HQ of 0.1 in the case of systemic toxicants.

4.3.2 Ecological Risk

This section provides the general methods used in the ERA for the OU-10 RI report. As summarized in Section 1.2.4, this RI addresses groundwater at all five of the EDA areas included in this report (EBPs, WBPA, NBPs, NBPLF, and FTP). The WBPA also addresses surface water and sediment within Spring Creek and perennial tributaries within its boundary. Soil is not evaluated at any of the areas, as this media was addressed under OU-1.

A screening level ecological risk assessment (SLERA) was conducted for all five IAAAP areas included in this RI report. The purpose of the SLERA is to determine the potential for adverse ecological effects associated with exposures to site-related chemicals in environmental media in the absence of remediation. The SLERA uses conservative assumptions to screen the initial list of detected chemicals to identify those requiring further evaluation. The results of the SLERA are provided in Section 5, by site.

Several guidance documents were used to provide direction for developing the SLERA. These include, but are not limited to, the following:

- *Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments, Interim Final* (USEPA, 1997b).
- *Final Guidelines for Ecological Risk Assessment* (USEPA, 1998a).
- *Ecological Risk Assessment and Risk Management Principles for Superfund Sites* (USEPA, 1999).
- *The Role of Screening Level Risk Assessments and Refining Contaminants of Concern in Baseline Ecological Risk Assessments* (USEPA, 2001b).
- *Wildlife Exposure Factors Handbook* (USEPA, 1993).
- *Environmental Quality Risk Assessment Handbook, Volume II: Environmental Evaluation* (USACE, 2010).
- *Final Uniform Federal Policy–Quality Assurance Project Plan for Remedial Investigation at Iowa Army Ammunition Plant, Middletown, Iowa* (UFP-QAPP) (CH2M, 2017).

In general, the approach and assumptions used in the SLERA are consistent with those provided in the final UFP-QAPP (CH2M, 2017), except for some deviations that were agreed to during meetings or correspondence with USACE and USEPA following approval of the final UFP-QAPP (i.e., use of the more current Region 4 ESVs instead of the QAPP-approved Region 5 ESLs as the primary source of screening values).

The USEPA provides a formal eight-step ERA process (USEPA, 1997b, 1998a), while not mandatory, it was followed to complete the SLERAs where applicable. It bears noting that this process is readily applied for CERCLA remedial investigations independent of considerations of the size, ecological relevance, or ecological significance of contaminated sites. Often however, a site may not need an ecological assessment based on the actual site features. The SLERA for the OU-10 RI followed the first two steps of the eight-step approach recommended by USEPA (1997b) as listed below:

- Step 1 of the ERA process is intended to answer two main questions: (1) Do complete exposure pathways exist? and (2) Are conservative screening levels available for the chemicals onsite to conduct the SLERA? If one or more complete exposure pathways are likely to exist, the ERA process continues to Step 2 for those pathways that have been determined to be critical. The available screening levels are then evaluated to determine whether they are adequate to evaluate the data in the SLERA. If not, additional screening levels are obtained from the scientific literature before the ERA process continues, or the ERA will be likely to move on to the refinement steps for chemicals or exposure routes lacking screening values.
- Step 2 of the ERA process involves conducting a screening exposure assessment, an effects assessment, and a risk calculation (risk characterization). The results of the SLERA are used to evaluate the potential for ecological adverse effects based upon very conservative assumptions. If the results of the SLERA suggest that further ecological evaluation or data collection is warranted, the ERA process then proceeds to the BERA (Steps 3 through 7), which is a more detailed phase of the ERA process, for the pathways, chemicals, receptors, and areas identified in the SLERA.

Following the SLERA, only the WBPA was carried to the BERA (see section 5.2.7). The following steps were conducted under the BERA:

- The first step of the BERA (Step 3) is the baseline problem formulation. The risk estimates from the SLERA are refined by the baseline problem formulation using more realistic exposure assumptions, and if adverse effects are still possible, the conceptual model and endpoints are refined to focus the subsequent steps of the ERA process.
- Following the completion of Step 3, a decision point is reached with two potential outcomes: (1) If the refined risk estimates are acceptable for each selected assessment endpoint, the investigation

advances to risk characterization (Step 7) to document this conclusion, and the ERA process terminates, or (2) the risk estimates indicate that adverse effects may exist and the ERA process continues (Steps 4 through 6). The additional data needed to support the ERA for the watersheds are presented in the approved UFP-QAPP (CH2M, 2018) and serve as the basis for Steps 4 through 6 of the ERA process.

The ERA process for the five IAAAP areas included in the OU-10 RI report began at Step 1 to determine if potentially complete exposure pathways are present at each site for the media included in this RI report (groundwater at all five areas and surface water and sediment at one area). The ERA for the OU-10 RI report only addresses aquatic environments. Terrestrial environments were not evaluated in the ERA as soil is not included in these OU-10 sites. There are perennial surface water features at three of the IAAAP areas in this RI report (EBPs, NBPs, and the WBPA). There are no perennial surface water features within the NBPLF or the FTP. Historically, ERAs have been conducted for various sites at IAAAP. In October 2004, a facility-wide BERA was conducted for soil, surface water, and sediment (MWH, 2004). The information available within the BERA regarding potential receptors, exposure routes, exposure factor values, and conclusions were reviewed and considered when developing the approaches and preliminary conceptual exposure models for the sites included in this RI.

4.3.2.1 Screening Level Problem Formulation (Step 1)

The screening level problem formulation establishes the goals, scope, and focus of the ERA. As part of the problem formulation, the environmental setting of the site is characterized in terms of the habitats and biota known to be or likely to be present. The types and concentrations of chemicals that are present in ecologically relevant media are also described based upon available analytical data. An ecological conceptual exposure model (ECEM) is developed that describes source areas, transport pathways and exposure media, exposure pathways and routes, and receptors. Assessment endpoints and measures are developed to evaluate those receptors for which ecologically significant exposure pathways exist.

Ecological Conceptual Exposure Model

Important components of the ECEM are the identification of potential source areas, transport pathways, exposure media, exposure pathways and routes, and receptor groups. The ECEM considered site-specific conditions that were observed at the IAAAP sites during RI field activities. A complete exposure pathway has three components: (1) a source of chemicals (stressors) that results in a release to the environment, (2) a pathway of chemical transport through an environmental medium, and (3) an exposure or contact point for an ecological receptor. In the absence of any one of these components, an exposure pathway is considered incomplete, and, by definition, there is no potential for adverse effects. Key components of this ECEM are discussed in the following subsections.

Transport Pathways and Exposure Media

A transport pathway describes the mechanisms whereby site-related constituents, once released, may be transported from a source to ecologically relevant media where receptor exposures may occur. Exposure media are the potentially contaminated media in which ecological receptors can come into contact. The primary mechanisms for transport from the source areas may include the following:

- Transport of chemicals via groundwater to sediment and surface water
- Surface water runoff with the potential to transport particulate-bound chemicals into the respective watershed, although this transport pathway is considered relatively minor
- Historical direct discharges

Exposure Pathways and Routes

An exposure pathway links a source of contamination with one or more receptors through exposure via one or more media and exposure routes. Exposure, and thus potential adverse effects, can occur only if a complete exposure pathway exists. An exposure route describes the specific mechanism(s) by which a receptor is exposed to a constituent present in an environmental medium.

Selection of Representative Species

To evaluate ecological exposure, representative species are selected for the functional feeding guilds identified in the ECEM. For example, a shrew may be considered representative of insectivorous mammals using the site. Consistent with *Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments, Interim Final* (USEPA, 1997b), these representative species should preferably be ones that have ecological relevance, are of societal value, are susceptible to chemical stressors at the site, and allow risk managers to meet policy goals. These factors were used to select representative species common to terrestrial habitats within IAAAP. The representative species selected for each feeding guild and habitat type are as follows:

- Freshwater aquatic biota (fish, amphibians, water column invertebrates, and benthic infauna).
- Freshwater aquatic plants.
- Piscivorous birds—belted kingfisher (*Ceryle alcyon*).
- Piscivorous mammals—mink (*Mustela vison*).
- Sensitive species (utilizing riparian corridor)—Indiana bat (*Myotis sodalis*) (as a representative species for bats in general within the watershed, including the Northern long-eared bat (*Myotis septentrionalis*).

Assessment Endpoints and Measures

The conclusion of the screening level problem formulation is the identification of assessment endpoints and measures. Assessment endpoints describe the valued ecological resources that are to be protected (USEPA, 1998a). Assessment endpoints are selected according to their ecological relevance, their susceptibility to known or potential stressors onsite, and whether they reflect management goals for the site.

Measures are quantifiable and are predictive of assessment endpoints. The three categories of measures are measures of exposure, measures of ecological effects, and measures of ecosystem and receptor characteristics (USEPA, 1998a). They evaluate, respectively, how exposures might occur, the response of the assessment endpoints when exposed to the stressor, and the ecosystem characteristics that might affect exposure or response to the stressor. This assessment will include both measures of exposure and measures of ecological effects. Appropriate assessment endpoints and measures include survival, growth, and reproduction. Measures, in the form of suitable screening benchmarks, are the ESVs discussed in Step 2.

4.3.2.2 Screening Level Risk Calculation (Step 2)

Available Analytical Data

Analytical data evaluation involved gathering and reviewing available site data and identifying a data set of acceptable quality for the SLERA. The historical data were evaluated to determine if they were likely to still be representative of current site conditions. The data set included in the SLERAs are discussed in Section 5. The data were evaluated using the following procedures:

- Unqualified results were considered detected.
- A value reported as “B” (blank contamination) or “J” (estimated) qualified was treated as a detected value.

- "U" (undetected) qualified results were treated as nondetected values.
- "R" (rejected) qualified results were not included in the SLERA data set.

For samples with duplicate analyses, the higher of the two concentrations was used when both values were detects or when both values were nondetects. In cases where one result was a detect and the other a nondetect, the detected value was used in the assessment. For nondetected results, the sample quantitation (reporting) limit (SQL) was used to represent the concentration. When calculating statistics (such as arithmetic mean), the SQL was used by ProUCL for nondetected results.

Screening Level Exposure Estimate and Risk Calculation (Step 2)

The screening level risk calculation is the final step in the SLERA. In this step, MDCs for each applicable medium at each site were compared with corresponding and conservative ESVs to derive screening risk estimates. For example, maximum medium-specific concentrations for all detected constituents were compared to risk-based screening values without considering the fraction of time a receptor forages within a site. If ESVs were unavailable, then the constituents were carried forward for further evaluation.

Ecological Screening Levels

The ecological SLs that were used are described in the following text; here are five possible outcomes from the comparison:

- If the maximum concentration(s) in a medium did not exceed the ESV, the chemical was not considered a COPEC.
- If the maximum concentration was greater than the ESV and the BTV, the chemical was identified as a COPEC.
- If no ESV was available, the chemical was selected conservatively as a COPEC depending upon rationale and potential former use.

The ESVs were obtained using the selection hierarchy in the order presented below.

- USEPA Region 4 ESVs (USEPA, 2018b).
- USEPA Region 5 Ecological Screening Levels (USEPA, 2003a).

In the approved UFP-QAPP, USEPA Region 5 ESVs were selected for ESVs. However, Region 4 values were used as the primary source since they are more current.

Screening Risk Calculation

In this step, the maximum ECs detected in sediment and surface water were compared with the corresponding ESVs to derive screening level risk estimates. Detected chemicals were evaluated using the HQ method. HQs were calculated by dividing the MDCs by corresponding ESVs. Chemicals with HQs greater than or equal to 1 and that are site-related were identified as COPECs and carried forward for additional evaluation. Detected chemicals for which ESVs were not available were also carried forward.

Each COPEC was then subjected to a weight-of-evidence evaluation in order to place the results for the COPECs into proper context and make one of the following decisions: (1) NFA is warranted, (2) further evaluation is warranted, or (3) additional data are required. Weight-of-evidence topics can include site size, nutrient considerations, exposure considerations, frequency of detection, magnitude of HQ, conservativeness of the ESV, ecological significance and comparisons using measures of central tendency (UCL and/or mean) in place of the MDC.

The assumptions used in the SLERA have inherent uncertainty. While it is possible that this leads to underestimates of potential adverse effects, the use of upper-bound assumptions most likely results in conservative estimates of potential adverse effects. A receptor group's potential exposure and subsequent potential adverse effects are influenced by the exposure scenario and dose/response and vary on a case-by-case basis. The general uncertainties associated with the SLERA are provided in Table 4.3-2. Site-specific uncertainties associated with each site are provided in Section 5.

Recommendation for Scientific Management Decision Point 1

Following Step 2, the first scientific management decision point occurs. This scientific management decision point is intended to communicate the findings of the SLERA and to determine which COPECs, representative species, and exposure pathways should be carried forward to Step 3. The approach for Step 3 and the BERA are described in the final UFP-QAPP (CH2M, 2017) and the draft Watershed ERA.

SECTION 5

Site-Specific Remedial Investigation

This section summarizes site-specific background information and site physical characteristics, RI activities, and investigation results for seven IAAAP sites (IAAP-012G, IAAP-032G, IAAP-003-R-01, IAAP-005-R-01, IAAP-036G, IAAP-037G, and IAAP-039G) within five areas at the EDA (EBPs, WBPA, NBPs, NBPLF, and FTP; see Section 1.2.4). Each site-specific section begins on a new page and is followed by its tables and figures.

The media addressed in this OU-10 RI at each area of the EDA is summarized as follows:

- **East Burn Pads (EBPs) (IAAP-012G):** This RI report addresses groundwater at the EBPs area. Soil at the EBPs is addressed under the remedy for OU-1 (IAAP-012) (Leidos, 2018). Although a very small reach of Spring Creek flows inside the western boundary of the EBPs, surface water and sediment are evaluated at the WBPA (IAAP-032G) because it is the site within the EDA containing the largest portion of Spring Creek and perennial tributaries within its boundary.
- **West Burn Pad Area (WBPA) (IAAP-032G, IAAP-003-R-01, and IAAP-005-R-01):** This RI report addresses groundwater, surface water, and sediment at the WBPA. Soil at the WBPA is addressed under the remedies for OU-1 (IAAP-032) (Leidos, 2018).
- **North Burn Pads (NBPs) (IAAP-036G):** This RI report addresses groundwater at the NBPs. Soil at the NBPs is addressed under the remedy for OU-1 (IAAP-036) (Leidos, 2018). Although a very small reach of Spring Creek flows inside the western boundary of the NBPs, surface water and sediment are evaluated at the WBPA (IAAP-032G) because it is the site within the EDA containing the largest portion of Spring Creek and perennial tributaries within its boundary.
- **North Burn Pad Landfill (NBPLF) (IAAP-037G):** This RI report addresses groundwater at the NBPLF. Soil at the NBPLF is addressed under the remedy for OU-1 (IAAP-037) (Leidos, 2018). There are no perennial surface water features within the NBPLF.
- **Fire Training Pit (FTP) (IAAP-039G):** This RI report addresses groundwater at the FTP area. Soil at the FTP area is addressed under the remedy for OU-1 (IAAP-039) (Leidos, 2018). There are no perennial surface water features within the FTP.

In accordance with the final UFP-QAPP (CH2M, 2017), screening values used for site characterization differ from those that used in the risk assessments. The site characterization PALs were used to assess the distribution and nature and extent of chemicals whereas more conservative screening values will be used for risk assessment. The site characterization PALs are discussed in Section 4.1.1.

5.1 East Burn Pads—Groundwater (IAAP-012G)

This subsection summarizes RI activities at the EBPs site within the EDA. This report documents the RI for groundwater at the EBPs (IAAP-012G). Soil is addressed under the remedy for OU-1 (IAAP-012) (Leidos, 2018). A very small reach of Spring Creek flows inside the western boundary of the EBPs. However, Spring Creek flows adjacent to several environmental sites within the EDA (Figure 5.1-1). Surface water and sediment are evaluated at the WBPA (IAAP-032G) (Section 5.2) because it is the site within the EDA containing the largest portion of Spring Creek and perennial tributaries within its boundary.). A limited discussion of surface water and sediment within Spring Creek is included in this section to support the CSM for the EBPs.

5.1.1 Background

5.1.1.1 Site Description

The EBPs compose an inactive site located in the northeast portion of the IAAAP facility that covers approximately 12 acres within the Spring Creek watershed (Figure 5.1-1). The EBPs are part of a larger area, the EDA.

The EBPs area was used for demilitarization by open burning. The site is fenced and there are no remaining structures onsite. The EBPs previously contained eight raised earthen burning pads (Pads 1E through 8E) that were surrounded by earthen berms to restrict horizontal movement of projectiles, with one side open for access (JAYCOR, 1996). An igloo/bunker (BG-11) was formerly located approximately 200 feet southwest, in line with the former burn pads, and was likely used to view burning activities at the EBPs. In 1998, contaminated soil was removed from the burn pads and surrounding area (Figure 5.1-1) (ECC 2000). Following excavations, the surface was regraded to the base of the pervious berms, and a layer of topsoil and vegetation was placed on the final grade.

5.1.1.2 Operational History

The EBPs were active between 1949 and 1982 for operations that included open burning of explosives-contaminated metals, propellants, explosives, and pyrotechnic-contaminated materials. Available documentation does not indicate that petroleum fuels or other liquid accelerants were used for open burning operations. Explosive powder that was used to initiate the flashing was spread on top of materials placed on the burn pads. Live ordnance was not demilitarized (Tetra Tech, 2006). Scrap metal was recovered for offsite recycling, and ash and other debris were disposed of offsite. Operations at the EBPs ceased once the EWI was constructed in 1982.

5.1.1.3 Previous Investigations and Remedial Actions

Numerous investigations have been conducted at IAAAP since the 1980s. Table 5.1-1 summarizes the previous investigations and remedial actions conducted at the EBPs, including conclusions and recommendations. Although soil at EBPs has already been addressed under OU-1, previous investigations for soil are also presented in Table 5.1-1 to support the CSM.

This report summarizes the RI for groundwater at the EBPs (IAAP-012G). Previous investigations pertinent to the RI for groundwater are listed below; additional details on these investigations (including a more detailed description of work completed, as well as work not pertinent to this RI), are included in Table 5.1-1. Previous groundwater sampling locations are shown on Figure 5.1-2.

Investigation	Conclusion
Contamination Survey (ERG, 1982)	Two monitoring wells (G-29 [EBPs] and G-30 [WBPA]) were installed, and groundwater was sampled for explosives. Groundwater samples collected at the EBPs did not contain explosives. Two surface water samples were collected from Spring Creek and analyzed for explosives. No explosives were detected in the samples.
Follow-on Study of Environmental Contamination (Battelle, 1984)	Two surface water samples were collected from Spring Creek upstream and downstream of the EDA and analyzed for explosives. No contamination was found in surface water at the EDA. No additional recommendations were made for the EDA sites.
Groundwater Study at the EDA (Army Armament Munitions Command, as reported in JAYCOR, 1994; Dames and Moore, 1986)	Four monitoring wells (EDA-1 through EDA-4) were installed around the EBPs. Groundwater samples were collected from five monitoring wells at the EBPs between 1984 and 1986 and analyzed for explosives, VOCs, and/or metals. Elevated levels of RDX were detected in EDA wells EDA-2 and EDA-4.
RCRA Facility Assessment (Ecology and Environment, 1987)	Three sediment samples were collected from the EDA and analyzed for explosives and metals. Significant levels of explosives (RDX, HMX, 1,3,5-TNB, and TNT) were detected. High metals concentrations were found upgradient and downgradient of the site. Additional sediment sampling was recommended.
Facility-wide Preliminary Assessment (JAYCOR, 1994)	The Preliminary Assessment indicated there was a potential for contamination at the EBPs. It was recommended that the extent of contamination near the EBPs should be confirmed and surface water and groundwater contaminant migration investigated.
Facility-wide Site Inspection (JAYCOR, 1992)	Four groundwater samples were collected at the EDA during the SI and were analyzed for explosives, metals, VOCs, and SVOCs. Groundwater from all four monitoring wells contained explosives. Metals were detected in three monitoring wells, and elevated VOCs were detected in one well (EDA-2). No SVOCs were detected in groundwater. Further investigation was recommended as part of the RI.
Phase I and Follow-on Remedial Investigation (JAYCOR, 1993, 1996)	Five existing monitoring wells and two newly installed piezometers (R12-PZ-06 and R12-PZ-07) were sampled for metals, explosives, VOCs, SVOCs, and/or pesticides/PCBs during Phase I. Six additional monitoring wells were installed and sampled during Phase II and follow-on RI activities for VOCs, SVOCs, explosives, and metals. In groundwater, explosives and metals were the main contaminants observed at the EBPs. The RI recommended semiannual compliance groundwater monitoring at five wells in the EBPs for VOCs, SVOC, explosives, and metals. A soil removal action was identified as being in progress at the EDA. Surface water and sediment samples were collected from four locations along Spring Creek (RBW-SW/SD-07, -10, -14, and -16). No explosives, VOCs, or SVOCs were detected in upstream samples or in downstream. Metals were detected at low levels in all samples.
Periodic Groundwater and Surface Water Monitoring (multiple reports)	Periodic groundwater and surface water sampling were conducted at the EBPs between the 1994 and 2007 as part of the FFA compliance monitoring and groundwater monitoring program. Samples were analyzed for VOCs, SVOCs, explosives, metals, and/or natural attenuation parameters. Explosives, primarily RDX, were detected above comparison criteria in shallow monitoring wells and upper bedrock wells at the EBPs. TCE was consistently detected at one overburden monitoring well. Five metals (arsenic, barium, cadmium, lead, and manganese) exceeded screening criteria more than once in a given well at the EBPs. Monitoring data for the EBPs indicate concentrations of explosives and VOCs have decreased or are stable.

Investigation	Conclusion
Supplemental Groundwater Remedial Investigation (MWH, 2001)	In 1997, groundwater samples were collected from 11 existing monitoring wells and analyzed for VOCs, SVOCs, explosives, and metals. RDX, TCE, methylene chloride, and bis(2-ethylhexyl)phthalate (two locations) exceeded screening levels. However, methylene chloride and bis(2-ethylhexyl) phthalate were attributed to laboratory or sampling contamination. It was concluded that RDX contamination was present in both shallow and bedrock monitoring wells; however, no deeper wells were present in the area to provide vertical delineation.
Additional Monitoring Well Installation (Harza, 2000)	Two new bedrock monitoring wells and one new shallow overburden well were installed and added to the groundwater monitoring program. Natural attenuation and gross alpha and gross beta were also included as analyses for the EBPs monitoring well network.
Feasibility Study Data Collection (URS, 2004a)	Groundwater samples were collected from 22 DPT borings and analyzed for VOCs and/or explosives. Groundwater samples were also collected from three new bedrock monitoring wells and analyzed for explosives, metals, VOCs, SVOCs, and natural attenuation parameters. VOCs and explosives were detected in DPT groundwater samples. VOCs, SVOCs, and metals were detected in the monitoring wells. The shallow groundwater explosives plume consisted primarily of RDX and was identified to be present under a large portion of the EBPs. No groundwater contamination was detected in bedrock or deep till above the screening criteria. Risk assessments were conducted using the groundwater data collected during the Feasibility Study investigation and the groundwater and surface water data collected during the periodic compliance monitoring events. RDX was identified as a groundwater COC while there were no COCs identified for surface water. Groundwater flow and contaminant fate and transport models were developed. The models predicted that RDX concentrations in groundwater should continue to decline over time due to naturally occurring processes. The initial natural attenuation concluded that natural attenuation processes may be occurring in the EBPs RDX plume.
Comprehensive Watersheds Evaluation and Supplemental Data Collection Work Plan (Tetra Tech, 2006)	The work plan concluded that no groundwater, surface water, or sediment data gaps were present at the EBPs.

SI = site inspection
TCE = trichloroethene

As part of the previous investigations under OU-1, explosives, VOCs, SVOCs, pesticides, PCBs, and metals were identified as soil COCs for the EDA (ECC 2000). Elevated levels of explosives (mainly RDX) were identified in soil around former burn pads, with the highest concentrations around Pad 8E (ECC, 2000); the former burn pad locations are shown on Figure 5.1-1. To address risks and hazards associated with these COCs, soil removal actions have been conducted at EBPs, and LUCs have been implemented (Leidos, 2019); excavation areas are shown on Figure 5.1-1. Confirmation samples verified that all soil COCs had been removed to OU-1 remedial goals, with the exception of RDX. In the areas where RDX exceeded its leachability remedial goal (Pads 1E, 2E, 4E, 5E, 6E, and 8E), an additional 1 to 2 feet of soil excavation was conducted. The final excavations were completed to depths of 1 to 10 feet bgs. Approximately 12,670 cubic yards of contaminated soil was removed from excavations around the eight burn pads. The USEPA and USACE approved the backfilling of these excavation areas given that additional removal was conducted, contaminant concentrations were low, the remaining contamination was deep in the soil profile and would be covered with clean soil, human health and ecological risk would be minimal at the site, and removal of additional soil considering the contaminant depth and low risk potential was not cost-effective (USACE, 2016). No additional confirmation samples or excavations were required according to the USEPA representative Scott Marquess (ECC, 2000).

5.1.2 2018–2020 Remedial Investigation Activities

Additional field work was conducted at the EBPs to resolve data gaps needed to complete the RI for groundwater (IAAP-012G). As documented in the final *Site-specific Worksheets for Operable Unit 6 of the Uniform Federal Policy–Quality Assurance Project Plan for Remedial Investigation at Iowa Army Ammunition Plant (Packet 2*) (CH2M, 2018a), explosives and arsenic required further horizontal and vertical delineation, particularly in the western portion of the site, and an improved understanding of current conditions was warranted to complete the RI. To address these data gaps, the installation of six overburden monitoring wells and five bedrock monitoring wells was proposed along with groundwater sampling of nine existing wells and the newly installed monitoring wells. Fieldwork completed at the EBPs was conducted in accordance with the UFP-QAPP (CH2M, 2018a).

Surface water monitoring of Spring Creek was also warranted to assess potential groundwater and surface water interactions (CH2M, 2018a). This field work was conducted under the WBPA investigation and is discussed in Section 5.2.

5.1.2.1 2018–2019 Field Activities

Between June 10 and August 16, 2018, six new monitoring wells—one overburden monitoring well (EBP-MW15) and five new bedrock monitoring wells (EBP-MW7, EBP-MW9, EBP-MW13, EBP-MW16, and EBP-MW17)—were installed at the EBPs to meet the data quality objectives (Figure 5.1-2). Installation of five additional monitoring wells in overburden locations (EBP-MW8, EBP-MW10, EBP-MW11, EBP-MW12, and EBP-MW14) were attempted; however, these locations were dry, and no wells were installed. Proposed and newly installed monitoring wells are summarized below.

Station ID	Groundwater Unit	Total Depth (Feet bgs)	Screen Interval (Feet bgs)	Rationale
EBP-MW7	Bedrock	62	45–55	To vertically delineate explosives near EDA-2.
EBP-MW8	Overburden	24.5	Dry, no well installed.	To horizontally delineate explosives and arsenic in overburden groundwater to the south-central portion of the RDX plume and downgradient of EBP-MW2 (arsenic).
EBP-MW9	Bedrock	61	50–60	To vertically delineate explosives and horizontally delineate arsenic in bedrock groundwater to the south-central portion of the RDX plume and downgradient of EBP-MW2 (arsenic).
EBP-MW10	Overburden	25	Dry, no well installed.	To horizontally delineate explosives in overburden groundwater south of the southwest lobe of the RDX plume.
EBP-MW11	Overburden	6 (refusal)	Dry, no well installed.	To horizontally delineate explosives in overburden groundwater west of the southwest lobe of the RDX plume.
EBP-MW12	Overburden	7 (refusal)	Dry, no well installed.	To horizontally delineate explosives in overburden groundwater north of the southwest lobe of the RDX plume.
EBP-MW13	Bedrock	62	50–60	To vertically delineate explosives southwest of the plume near EDA-2.

Station ID	Groundwater Unit	Total Depth (Feet bgs)	Screen Interval (Feet bgs)	Rationale
EBP-MW14	Overburden	14	Dry, no well installed.	To horizontally delineate explosives in overburden groundwater northwest of the northwest lobe of the RDX plume near EBP-MW4.
EBP-MW15	Overburden	37	27–37	To horizontally delineate explosives in overburden groundwater to the north-centralportion of the RDX plume.
EBP-MW16	Bedrock	52	25–35	To vertically delineate explosives in bedrock groundwater northwest of the northwest lobe of the RDX plume near EBP-MW4.
EBP-MW17	Bedrock	51	40–50	To vertically delineate explosives in bedrock groundwater west of the southwest lobe of the RDX plume near EBP-MW5.

New monitoring wells were drilled via rotosonic drilling techniques with a MiniSonic drill rig and 6-inch drill rods (overburden) and wireline (bedrock) or with a Geoprobe 6620DT drill rig with 6- and 8-inch-outer-diameter augers (shallow overburden) in accordance with Section 3.2.3. Boring logs are provided in Appendix C. For monitoring well pairs, overburden lithology was logged only at the proposed overburden locations. All proposed overburden monitoring well locations were drilled to bedrock or refusal. Bedrock monitoring well locations were drilled to depths between 50 and 62 feet bgs, which is consistent with the UFP-QAPP (CH2M 2018a).

As summarized in the table above, groundwater was generally not present in the overburden at the EBPs, and only one new monitoring well (EBP-MW15) could be installed within this aquifer unit. In accordance with the UFP-QAPP, the overburden monitoring well (EBP-MW15) was screened across the perceived water table, just above bedrock. Well construction details are provided in Table 5.1-2. EBP-MW15 was completed with a 2-inch-nominal-diameter Schedule 40 PVC screen and riser and 0.5-foot Schedule 40 PVC end cap. The monitoring well was screened with a machine-slotted 0.010-inch, 10-foot screen. The monitoring well was constructed with a certified-clean silica sand filter pack from the base of the borehole to 2 feet above the top of the screen. A 3-foot-thick bentonite layer was placed above the filter pack sand and hydrated. The well was grouted to the surface, and a steel stickup well protector was installed and surrounded by three bollards. Well completion diagrams are included in Appendix C.

Bedrock monitoring well borings were cored up to 62 feet bgs to look for groundwater presence in the bedrock cores. Based on field observations (such as fracture frequency and moisture content), the bedrock wells were screened across intervals that were the most likely to produce groundwater. Once the screen interval was selected, the borings were reamed with 6-inch drill rods via sonic drilling techniques to the identified monitoring well depth. EBP-MW16 was overdrilled during reaming and was backfilled to 36 feet bgs with a bentonite seal following reaming activities. Well construction details are provided in Table 5.1-2. Bedrock monitoring wells were completed with a 2-inch-nominal-diameter Schedule 40 PVC screen and riser and 0.5-foot Schedule 40 PVC end cap. Bedrock monitoring wells were screened with a machine-slotted, 0.010-inch, 10-foot screen. Centralizers were installed at the base and just above the screened interval. Monitoring wells were constructed with a certified-clean silica sand filter pack from the base of the reamed borehole to 2 to 5 feet above the top of the screen. A 3- to 5-foot-thick bentonite layer was placed above the filter pack sand and hydrated. The well was grouted to the surface, and a steel stickup well protector was installed and surrounded by three bollards. Well completion diagrams are included in Appendix C.

In August 2018, newly installed monitoring wells were developed as described in Section 3.2.4. EBP-MW15 was developed on August 5, 2018, and EBP-MW7, EBP-MW9, EBP-MW13, EBP-MW16, and EBP-MW17 were developed on August 21, 2018. All monitoring wells were purged dry at least once. All EBP monitoring wells were considered developed due to the slow recharge. Well development logs are provided in Appendix C.

Groundwater samples were collected from 15 existing and newly installed monitoring wells between June 2018 and March 2019. Three existing monitoring wells (EBP-MW4, EBP-MW5, and EDA-4) were sampled between June 24 and July 12, 2018. Groundwater samples were collected for explosives by Method SW8330B. Newly installed monitoring wells (EBP-MW7, EBP-MW9, EBP-MW13, EBP-MW15, EBP-MW16, and EBP-MW17) were sampled between March 6 and 25, 2019. Additionally, six existing monitoring wells (EBP-MW2, EBP-MW3, EBP-MW6, EDA-1, EDA-2, and JAW-07) were sampled between March 6 and 8, 2019. All groundwater samples at the EBPs were sampled via low-flow purging and sampling techniques or by purging three casing volumes. Groundwater samples were collected for explosives by Method SW8330B. Groundwater samples from EBP-MW2, EBP-MW3, EBP-MW9, and EDA-2 were also collected for arsenic by Method SW6020A and groundwater samples from EBP-MW13 were also collected for VOCs by Method SW8260 to support VOC delineation at the WBPA (discussed further in Section 5.2). Purge logs are included in Appendix C. Data were managed and validated as discussed in Section 3.3. Laboratory reports are provided in Appendix B.

All IDW generated during activities (soil and purge water) was disposed of in accordance with management activities discussed in Section 3.2.9. Waste management documentation is provided in Appendix D.

Newly installed monitoring wells EBP-MW7, EBP-MW9, EBP-MW13, EBP-MW15, EBP-MW16, and EBP-MW17 were surveyed by Bruner, Cooper, and Zuck, Inc., licensed Iowa surveyors, on September 24, 2018, in accordance with the methods described in Section 3.2.7. Survey information is included in Appendix E.

5.1.2.2 Deviations and Follow-on Field Activities (2020)

The final UFP-QAPP (Packet 2) (CH2M, 2018a) proposed the installation of 11 new monitoring wells (four overburden/bedrock well pairs, two overburden monitoring wells, and one bedrock monitoring well) to delineate the explosives and arsenic plumes at the EBPs. However, due to the thinness of the overburden unit in this area of IAAAP and the lack of groundwater in the overburden, only one out of the six proposed overburden monitoring wells were installed, as detailed in Section 5.1.2.1. This did not impact the results of the RI since the lack of groundwater in the overburden provides the necessary conceptual site model information.

One existing monitoring well (JAW-06) could not be sampled because the well was damaged. Therefore, a replacement monitoring well, JAW-06R, was installed on May 12, 2020, approximately 5 feet northwest from former JAW-06. The replacement well was drilled via hollow-stem auger drilling techniques using a Geoprobe 8040DT drill rig with 6-inch-outer-diameter augers in accordance with methods described in Section 3.2.3. The boring was drilled to 28.5 feet bgs, a depth similar to the original well, JAW-06. The boring log is provided in Appendix C. Based on lithologic observations, JAW-06R was screened from 18 to 28 feet bgs. The replacement well was completed with a 2-inch-nominal-diameter Schedule 40 PVC screen and riser and 0.5-foot Schedule 40 PVC end cap. The monitoring well was screened with a machine-slotted, 0.010-inch, 10-foot screen. The monitoring well was constructed with a certified-clean silica sand filter pack from the base of the borehole to 2 feet above the top of the screen. A 3-foot-thick bentonite layer was placed above the filter pack sand and hydrated. The well was grouted to the surface, and a steel stickup well protector was installed and surrounded by three bollards. Well completion diagrams are included in Appendix C. The installation and sampling of replacement well JAW-06R did not impact the results of the RI since the location was among the proposed sample locations and was still able to be sampled using the newly installed well.

On June 4, 2020, newly installed replacement monitoring well JAW-06R was developed in accordance with methods described in Section 3.2.4. JAW-06R was purged dry after approximately four well casing volumes were extracted, and the well was considered developed due to the slow recharge. Well development logs are provided in Appendix C.

A groundwater sample was collected from the replacement well on June 10, 2020. Because only a limited amount of groundwater had reentered the well following well development due to slow aquifer recharge, the sample was collected using a well bailer instead of a pump. No groundwater parameters were collected during sampling. The groundwater sample was analyzed for explosives by Method SW8330B. Data were managed and validated as discussed in Section 3.3. Laboratory reports are provided in Appendix B.

All IDW generated during activities (soil and purge water) was disposed of in accordance with management activities discussed in Section 3.2.9. Waste management documentation is provided in Appendix D. Newly installed replacement monitoring well JAW-06R was surveyed by Bruner, Cooper, and Zuck, Inc., licensed Iowa surveyors, on June 2, 2020, in accordance with methods described in Section 3.2.7. Survey information is included in Appendix E.

5.1.3 Environmental Setting

5.1.3.1 Topography and Surface Water

The topography over most of the EBPs site consists of an elevated, relatively flat area that slopes to the southwest towards Spring Creek. In the northeast portion of the EBPs, the topography slopes to the east toward an intermittent tributary. Following the soil removal actions, the area of the former burns pads was regraded to the base of the pervious berms. Surface elevations at the EBPs range from 640 feet amsl at Spring Creek to approximately 690 feet amsl in the northeastern portion of the site. West of the EBPs, the landscape is dissected by Spring Creek, and the topography changes to a steeply sloping terrain (URS, 2004a).

Surface runoff from the majority of the EBPs is channeled into shallow, intermittent drainage ditches and flows west toward Spring Creek and south into a south-flowing ephemeral tributary of Spring Creek (Figure 5.1-1). Surface runoff from the northeastern portion of the site flows east and into the southeast-trending segment of an intermittent tributary of Spring Creek.

5.1.3.2 Geology and Hydrogeology

The geology of the EBPs consists of unconsolidated overburden overlying limestone and shale bedrock. The unconsolidated overburden consists of loess and glacial till. A clayey silt loess has been observed in some borings in this area up to depths of 4 to 6 feet bgs, overlying the glacial till (Tetra Tech, 2006). The glacial till has been characterized as a silty clay to sandy clay with fine- to medium-grained sand with localized discontinuous sand seams or lenses. In the vicinity of Spring Creek, to the west of the EPBs, the glacial till pinches out. The overburden is underlain by bedrock at depths ranging from 5 to 53 feet below bgs; however, two historical borings (EPB-MW2 and EBP-DP-02) identified depth to bedrock considerably deeper, at 143 and 99 feet bgs, respectively. Generally, bedrock is shallower on the west side of the EBPs toward Spring Creek. The bedrock consists of limestone and shale associated with the Warsaw Formation and possibly the upper portions of the Keokuk Limestone, and outcrops along the banks of Spring Creek, where the glacial till pinches out. At monitoring wells EBP-MW4 and EBP-MW5, installed near Spring Creek, the upper bedrock thickness measured approximately 15 to 20 feet, was moderately to highly weathered, and contained isolated voids; rock quality designations ranged between 60 and 70 percent. Below the weathered and fractured bedrock zone, the bedrock becomes more competent; for example, at EBP-MW6, the rock quality designation in the screened interval was 100 percent (URS, 2004a).

Groundwater at the EBPs is divided into two units, overburden and bedrock groundwater. As previously discussed, the glacial till (overburden) pinches out to the west and can be locally absent. It increases in thickness to the east since the interface between the overburden and bedrock is tilted, sloping towards the east. In addition, groundwater is generally present only in the overburden at the EDA where sand seams are present. As a result, groundwater can be absent from the overburden unit at the EDA. Where present, overburden groundwater is monitored by wells screened between approximately 7 and 143.5 feet bgs, and groundwater levels measured during this RI in 2019 ranged from 5 to 20 feet below top of casing (btoc) (Table 5.1-3). Historically, groundwater at the EBPs has ranged from less than 1 to approximately 35 feet bgs. Bedrock groundwater is monitored by monitoring wells screened between approximately 13 and 75 feet bgs, with groundwater levels ranging from approximately 11 to 32 feet btoc in 2019. The deepest bedrock well at the site is shallower than the deepest overburden well because the overburden thickness at this site is highly variable, and the bedrock outcrops out at the surface near the creek, as depicted in Figure 5.1-8. Therefore, depths and elevations cannot be used as an indicator of what geologic zone a well is screened in at the EDA. Groundwater flow in the upper, weathered, bedrock generally occurs in the fractures and voids contained in the rock while groundwater flow in the competent bedrock is limited (URS, 2004a).

Based on recent and historical groundwater gauging data, shallow groundwater generally flows southwest toward Spring Creek (Figure 5.1-3). In the northeastern portion of the site, groundwater flows more to the east, where the topography changes to slope eastward (Figure 5.1-3). Calculated horizontal hydraulic gradients were approximately 0.05 foot/foot (ft/ft) in the EBPs. Based on 2019 groundwater elevations, a downward vertical gradient of -0.13 ft/ft was observed at the well pair EDA-2 (bedrock well) and EBP-MW7 (interface well); groundwater elevations are provided on Table 5.1-3.

Hydraulic conductivities of overburden and bedrock groundwater have been estimated from slug tests. Hydraulic conductivity of shallow glacial till groundwater ranged from 0.0013 to 0.55 foot per day (ft/day), and calculated conductivities in deep till (EBP-MW2) ranged from 0.38 to 8.6 ft/day. Calculated conductivities of bedrock groundwater ranged from 0.00015 to 0.025 ft/day (URS, 2004a).

5.1.3.3 Groundwater–Surface Water Interaction

Historically, groundwater gauging data associated with the spring and fall 2006 gauging events, in which the surface water elevation of the creek was also evaluated, indicated a potential for groundwater discharge to surface water along Spring Creek at the EBPs. Groundwater elevations of two monitoring wells, EBP-MW4 (screened from 34.5 to 44.5 feet bgs) and EBP-MW5 (screened from 35 to 45 feet bgs), located about 300 feet from Spring Creek, were compared to the nearby elevations of Spring Creek. Water levels observed in 2006 at EBP-MW4 show that the water table was between 3 and 6 feet higher than the nearby elevation of Spring Creek. At EBP-MW5, the water levels showed that the water table ranged from 4 feet below to 5 feet above the nearby elevation of Spring Creek, indicating that groundwater periodically discharges to the reach of Spring Creek adjacent to the EBPs (Figure 5.1-3). In contrast, the May 2015 groundwater gauging data indicated that Spring Creek and its ephemeral tributary are losing water to groundwater. Therefore, groundwater–surface water interaction is likely dependent on the temporal variability in groundwater elevations. Figure 5.1-8 shows the intersection of Spring Creek with the potentiometric surface.

Between staff gauge installation in 2018 and the 2019 RI gauging event, the three new staff gauges (EDA-1 through EDA-3) were damaged, and accurate measurements could not be recorded during the sitewide gauging event. It is recommended that these staff gauges be repaired to obtain accurate measurements in the future.

5.1.4 Nature and Extent of Contamination

This subsection describes the nature and extent of groundwater contamination at the EBPs (Figures 5.1.4 and 5.1.5). Surface water and sediment data from the vicinity of the EBPs (Figure 5.1-6) is also discussed to support the fate and transport evaluation. Similarly, although soil has been addressed under OU-1, a summary of the soil COCs is discussed briefly to inform the CSM for potential groundwater contaminants.

The source of contamination at the EBPs is attributed to releases to the surface as a result of historical site operations, including open burning of metals, propellants, explosives, and pyrotechnic-contaminated materials (URS, 2004a). Incomplete combustion of explosives compounds and metals from ash released to soil may have leached into groundwater.

5.1.4.1 Groundwater

Groundwater samples have been collected at the EBPs since 1981. Twenty-three active monitoring wells are present at the EBPs. Ten of the wells are screened in the overburden to depths ranging from 15.5 to 143.5 feet bgs, one well is screened across the overburden bedrock transition zone from 12 to 27 feet bgs, and 12 are screened in bedrock at depths ranging from 13 to 75.1 feet bgs (Figure 5.1-1). Historical groundwater samples were analyzed for VOCs, SVOCs, PAHs, explosives, metals, PCBs, radionuclides, and pesticides/herbicides. No pesticides or PCBs were detected in historical groundwater samples, and PAHs have not been detected in groundwater sampled since 1992 at the EBPs. Based on historical site operations and COCs identified in soil, explosives, VOCs, and metals are considered chemicals of interest in groundwater at the EBPs.

Samples were collected from 16 monitoring wells during the most recent RI activities, between 2018 and 2020, and analyzed for explosives (Figure 5.1-4). Monitoring well EBP-MW13 was also analyzed for VOCs, and monitoring wells EBP-MW2, EBP-MW3, EBP-MW9, and EDA-2 were also analyzed for arsenic to address the data quality objectives. Table 5.1-4 summarizes the chemicals detected in groundwater between 2000 and 2020 sampling events at the EBPs. Summary tables of all the analytical results (including nondetects) from the 2018–2020 RI activities are provided in Appendix G. Summary tables of all historical analytical results from the EBPs are provided in Appendix H.

VOCs

Thirteen VOCs have been detected in groundwater at the EBPs since 2000 (Table 5.1-4). Of these, only TCE has exceeded the site characterization PAL at one location, JAW-06. However, while TCE was detected above its PAL in JAW-06 in 2000 and 2001, it was detected below its PAL (5 µg/L) in this same well during subsequent sampling events in 2002 through 2006. Downgradient monitoring well EBP-MW13 was sampled for VOCs during the 2018–2020 RI (Figure 5.1-5); the only VOC detected in the well was acetone at a concentration below its site characterization PAL. There have been no VOC exceedances in groundwater at the EBPs since 2001.

SVOCs

Ten SVOCs have been detected in groundwater at the EBPs since 2000 (Table 5.1-4). Of these, only bis(2-ethylhexyl)phthalate exceeded its site characterization PAL (6 µg/L). Exceedances were reported in 11 monitoring wells in 2000; however, during subsequent sampling events in 2001 and 2002, bis(2-ethylhexyl)phthalate was nondetect at all 11 of these locations. Bis(2-ethylhexyl)phthalate is a plasticizer that is used in many common products, including PVC, plastic syringes, and pipette tips. It is not known to have been used at IAAAP. Therefore, its historical presence is attributed to laboratory or sampling contamination.

Explosives

Between 2000 and 2020, eight explosives were detected at the EBPs (Table 5.1-4). During the most recent RI monitoring event (2018–2020), only RDX exceeded its site characterization PAL at four locations (EBP-MW3, EBP-MW4, EBP-MW5, and EDA-2), as shown on Figure 5.1.4. In previous sampling events in 2007 and 2008, RDX also exceeded its PAL in EDA-3 and EDA-4. Since 2007, RDX concentrations have been decreasing at all monitoring wells except EBP-MW4, where concentrations increased from

4.9 µg/L in 2007 to 47 µg/L in 2018, although concentrations at this location have fluctuated since 2003 (Figure 5.1-7). EDA-3 was not sampled in during the recent RI activities (2018–2020). The maximum RDX concentration was detected at EDA-2 (149 µg/L) in 1985, and in 2019 RDX concentrations at this location had decreased to 13 µg/L.

RDX is present predominantly in overburden across the EBPs. However, in the area where the overburden aquifer pinches out, groundwater is not present, and the overburden aquifer is absent. As previously discussed, attempted overburden monitoring wells were dry in the western portion of the site. Where groundwater is present in the overburden, the RDX plume vertically extends to approximately 25 feet bgs in this aquifer (Figures 5.1-8 and 5.1-9). Where the overburden pinches out, three bedrock monitoring wells were installed to delineate the plume along the western boundary; bedrock monitoring wells EBP-MW13, EBP-MW16, and EBP-MW17 were screened between 25 and 50 feet bgs. Out of these locations, RDX was detected only in EBP-MW16 (screened 25 to 35 feet bgs), at a concentration of 0.36 J µg/L, below the site characterization PAL, indicating the western edge of the RDX plume is adequately delineated. RDX concentrations were nondetect at EBP-MW15, EDA-1, JAW-06R, JAW-07, and EBP-MW9 to the north, east, and south of the RDX plume (Figure 5.1-4). RDX concentrations were also nondetect at EBP-MW2 and EBP-MW6, which are screened between approximately 65 and 143 feet bgs, providing vertical delineation.

Metals

Thirteen metals have been detected in groundwater at the EBPs since 2000; however, only chromium was detected above its site characterization PAL (100 µg/L) and BTV (31 µg/L). Chromium historically exceeded its PAL and BTV in one location, EBP-MW1, in 2000 (126 µg/L). However, during subsequent sampling events in 2000, 2001, and 2002, chromium was either not detected or detected below the PAL and BTV at this location.

Concentrations of some metals may be naturally elevated in the environment, and may not indicate a CERCLA-regulated release. Several metals (such as arsenic, chromium, and manganese) were detected at levels below their BTVs during the latest sampling events and are therefore considered to be naturally occurring in groundwater at the EBPs. Although cobalt does not have a BTV, its presence in groundwater is also not considered to be site-related. Cobalt was detected in two monitoring wells (JAW-06 and EDA-2) in the early 1990s; however, it was nondetect in the same wells during subsequent sampling events. In a more recent sampling event in 2006, cobalt was reported in one well (EBP-MW06) at a low concentration, of 3.8 B µg/L (Appendix H). The B qualifier indicates that cobalt was also detected in the associated method and/or calibration blank, and this monitoring well concentration is likely biased high. The lines of evidence indicate that cobalt in groundwater is not associated with a site release at the EBPs.

Radionuclides

Gross alpha and gross beta have been detected in groundwater samples collected at the EBPs. The highest activities were observed in former overburden well JAW-06 (gross alpha of 8.2 picocuries per liter [pCi/L] and gross beta of 11.5 pCi/L in December 1999) and bedrock well JAW-04 (gross alpha of 12.8 pCi/L and gross beta of 11 pCi/L in May 2000). All concentrations were below the gross alpha MCL (15 pCi/L) and gross beta MCL (50 pCi/L) (Table 5.1-4).

5.1.4.2 Sediment and Surface Water

There is a very small segment of Spring Creek that runs just inside the western boundary of the EBPs. Spring Creek also flows adjacent to the outside portions of the northwestern site boundary and the southwestern site boundary (Figure 5.1-1). This creek and its perennial tributaries are predominantly located within the WBPA, and therefore, these surface water features are discussed in more detail in Section 5.2. However, to support the CSM for the EBPs, the nature and extent of RDX in surface water and sediment samples that are near the EBPs are discussed in this subsection.

Figure 5.1-6 shows surface water and sediment samples that have been collected from the EDA for explosives analysis. During the 2018 to 2020 RI sampling event, explosives were collected upstream (EDA-SW03) and downstream (EDA-SW02) of the EBPs. RDX was not detected in any of the upstream or downstream surface water samples. As described above, RDX has also been delineated at the EBPs along the western site boundary, providing further evidence that groundwater contamination at the EBPs is not discharging to Spring Creek.

5.1.5 Fate and Transport

This section discusses the fate and transport of site-related chemicals of interest at the EBPs. This includes chemicals that were detected above both their site characterization PAL and BTV (if available) during the last sampling event that those chemicals were analyzed. In groundwater, the only potential site-related chemical of interest is RDX. Fate and transport characteristics for this chemical are described in Section 3.2.

The EBPs were formerly used for demilitarization by open burning. The site is fenced and is vegetated, with no remaining structures onsite. This site falls within the Spring Creek watershed (Figure 2-1), and Spring Creek runs along the western boundary of the site (Figure 5.1-1). Surface water drainage occurs through a number of intermittent drainage ditches that ultimately discharge to Spring Creek. The groundwater at the EBPs is divided into two units, overburden and bedrock groundwater. However, the overburden aquifer is absent along the western portion of the site where the overburden pinches out and bedrock outcrops at the surface. Groundwater levels measured in the overburden aquifer ranged from 5 to 20 feet bgs (Figure 5.1-3), although historically groundwater has ranged from less than 1 to approximately 35 feet bgs. Bedrock groundwater levels ranged from approximately 11 to 32 feet bgs in 2019.

The source of contamination at the EBPs is attributed to unintended releases to the surface as a result of historical site operations, including open burn operations. Contaminants in groundwater have been transported from the source release areas through advection and dispersion. Groundwater generally flows towards Spring Creek, however a component of groundwater in the northeastern portion of the site flows eastward (Figure 5.1-3). Hydraulic conductivity of the overburden geology ranged from 0.0013 to 0.55 ft/day during aquifer slug testing in 2003. Calculated conductivities of bedrock groundwater ranged from 0.00015 to 0.025 ft/day (URS, 2004a). The groundwater flow velocities at the EBPs were estimated on the basis of the aquifer slug tests' results. As expected, the groundwater flow velocities were slow and ranged from 0.4 to 5.9 feet/year in the shallow overburden and from 0.0016 to 25 feet/year in the bedrock. Vertical migration at the site is also limited by the generally tight clay lithology in the overburden.

Natural attenuation mechanisms that are potentially active at the EBPs were evaluated. Natural attenuation includes various physical, chemical, or biological processes that under favorable conditions act without human intervention to reduce the mass, toxicity, mobility, volume, or concentration of contaminants in groundwater. A weight-of-evidence approach was used for this evaluation.

- The primary line of evidence that attenuation is occurring at a site is reduction over time in contaminant concentrations or mass, or both. Explosives were only detected above their site characterization PALs in four overburden and shallow bedrock monitoring wells during the latest sampling events (EBP-MW3, EBP-MW4, EBP-MW5, and EDA-2). RDX concentrations in three out of the four wells have decreased since late 2007 (Figure 5.1-7). Historically, the highest concentrations of RDX were detected at overburden monitoring well EDA-2; however, concentrations have been decreasing at this location since approximately 2000 (Figure 5.1-7). This decrease in concentrations indicates that natural attenuation may be occurring in this source area well. However, increasing trends at EBP-MW4 and EDA-3, both located near the leading edge of the RDX plume, may be indicative of some plume migration. Nevertheless, the lack of RDX exceedances in the most downgradient wells (EBP-MW13, EBP-MW16, and EBP-MW17) and surface water samples indicate that any plume migration is slow and limited.

- Anaerobic daughter products of RDX were detected at the EBPs in 2018. Low levels (less than 5 to 16 J µg/L) of MNX, TNX, and DNX were detected at monitoring wells EBP-MW3, EBP-MW4, EBP-MW5, EDA-2, EDA-3, and EDA-4, providing evidence that anaerobic biodegradation of RDX is occurring at the EBPs.
- Water quality parameters can be used to evaluate whether the geochemical conditions are conducive to biodegradation. During the current RI, groundwater in the impacted monitoring wells in the RDX plume (EBP-MW3, EBP-MW4, EBP-MW5, and EDA-2) was observed to be under aerobic and oxidizing conditions. Dissolved oxygen (DO) concentrations were reported in groundwater between 0.77 and 4.04 mg/L, and oxidation-reduction potential (ORP) values were reported above generally +100 mV (Tables 5.1-5). pH values were relatively neutral (between 6 and 7), which is favorable for biological activity. Under these geochemical conditions, anaerobic biodegradation of explosives, particularly RDX, would be less favorable. Nevertheless, the presence of anerobic RDX daughter products (MNX, DNX, TNX) indicates that anaerobic biodegradation has occurred. RDX is also subject to abiotic degradation.

The physical natural attenuation processes are also likely helping to attenuate plume migration. While the RDX in groundwater has moderate solubility and relatively low sorption potential, it should be retarded somewhat, as it sorbs to the clay geology. The decreasing thickness, of the overburden aquifer in this western direction may also be a factor that is limiting plume migration. RDX has limited volatility (Table 4-1) and therefore is unlikely to volatilize into soil gas at the water table interface.

5.1.6 Human Health Risk Assessment

An HHRA was prepared for the EBPs to evaluate potential current and future health risks and hazards from exposure to chemicals in site groundwater. Soil media within the EBPs is not included in the HHRA, as it is not a component of this RI; soil is addressed under the remedy for OU-1 (IAAP-012) (Leidos, 2018). A brief summary of OU-1 soil COCs is provided in Section 5.1.1.3 and historical remedial activities for soil are presented in Table 5.1-1. Spring Creek runs along the boundary between the WBPA and the EBPs, and this perennial feature is further evaluated in Section 5.2.6, with the WBPA. The EBPs HHRA was conducted in accordance with the final UFP-QAPP (CH2M, 2017), with the exception of some deviations that were agreed to during meetings or correspondence with USACE and USEPA following approval of the final UFP-QAPP. The approach and method used to conduct the HHRA are provided in Section 4.3.1. This section presents the CEM for the EBPs and provides the results of the four-step evaluation process comprising the following:

- Data evaluation.
- Exposure assessment.
- Toxicity assessment.
- Risk characterization.

The results of the HHRA are used to determine if further action is warranted for groundwater at the EBPs.

5.1.6.1 Conceptual Exposure Model

A description of the EBPs, their operational history, previous investigations, and remedial actions are provided in Sections 5.1.1 and 5.1.2.

The EBPs is an inactive site. Demilitarization by open burning was performed at the EBPs site. The site is fenced, and there are no remaining structures onsite. The site is open to recreational activities, and hunting is permitted within the site boundary. Spring Creek runs along the boundary between the WBPA and the EBPs. Exposures to Spring Creek surface water and sediment are addressed in the WBPA HHRA, Section 5.2.6. There are no other perennial surface water features within the EBPs. Culverts are present at the site; therefore, potential groundwater exposures by future construction/utility workers are complete at the EBPs.

Groundwater is not currently being used as a potable water source, and there are no plans to use groundwater for potable purposes in the future; however, based on applicable CERCLA policy and guidance, groundwater at the EBPs is classified as Class IIB, a potential source of drinking water (USEPA, 1989). Therefore, the HHRA for the EBPs evaluates potential exposures to groundwater due to its potential future use as a drinking water source. This consists of the evaluation of future residential exposures to groundwater.

There are no potentially complete exposure pathways under current site conditions. The following potential future human receptors were identified in the HHRA for the EBPs:

- **Future Site Workers.** Future site workers could contact groundwater based on its potential future use as a drinking water source at the EBPs and could be exposed to indoor air (that may be impacted by volatile chemicals migrating from groundwater) in buildings.
- **Future Construction/Utility Workers.** Future construction/utility workers could contact shallow groundwater while replacing a culvert located within the EBPs.
- **Future Hypothetical Residents.** Future hypothetical residents could contact groundwater based on potential future use as a drinking water source at the EBPs and could be exposed to indoor air (that may be impacted by volatile chemicals migrating from groundwater) in buildings.

As discussed in Section 4.3.1, potential exposures and risks and hazards to future site workers and construction/utility workers are estimated in the HHRA only if the estimated risks and hazards for a hypothetical residential scenario exceed acceptable risk levels and COCs are identified for a residential scenario. The human health CEM presenting potential exposure media, exposure points, receptors, and exposure routes is provided in Appendix A-2, Attachment 1 (Table 1), and depicted graphically on Figure 5.1-10.

5.1.6.2 Data Evaluation

Data Used in the HHRA

Historical groundwater samples collected from 2003 and 2005 to 2008 and recent groundwater samples from 2018 to 2020 were used in the HHRA for the EBPs. The groundwater samples collected in 2003 were analyzed for explosives, metals, PAHs (all nondetects), SVOCs, and VOCs; 2005 and 2006 samples were analyzed for explosives, metals, an SVOC (1,4-oxathione), and VOCs; 2007 and 2008 samples were analyzed for arsenic and RDX; 2018 and 2020 samples were analyzed for explosives; and 2019 samples were analyzed for explosives, arsenic, SVOCs (all nondetects), and VOCs. With the exception of six samples,[5] only metals, SVOC and VOC data from the 2003 to 2008 data were used in HHRA because more recent explosives data were available. As stated in the UFP-QAPP (CH2M, 2017), “Older data (i.e., data collected prior to 2012) may be used in the human health risk assessments if they are still representative of the site (i.e., groundwater flow is slow), chemicals have properties where there would not be a significant reduction in concentrations over time (e.g., metals), or data are conservative for site conditions.” The EBPs are no longer operational, as described in Section 5.1.1. Potential soil sources to groundwater have been remediated, as described in Section 5.1.1.3. Due to a lack of continuing sources, historical concentrations in groundwater are expected to have remained stable or even decreased due

[5] Explosives data from the following samples were included in the HHRA: EBP-MW1-20030528, G-29-20030531, JAW-04-20030530, JAW-05-20030531, JAW-614-20030601, and JAW-64-20030531.

to natural attenuation processes. Therefore, the assumptions in the final UFP-QAPP still hold. Samples collected prior to 2012 are considered representative of, or more conservative than, current conditions at the EBPs.

A total of 73 groundwater samples were used to evaluate potential exposures for both a potable use scenario and the VI pathway. The groundwater samples were not collected at multilevel wells; therefore, a separate data grouping (based on shallow groundwater only) was not used to evaluate the VI pathway. A summary of the number of chemicals analyzed and detected in groundwater is presented below:

Chemical Group	Number of Chemicals Analyzed	Number of Chemicals Detected
Explosives	17	6
Metals	23	18
PAHs	1	0
SVOCs	47	1
VOCs	65	7

Data groupings and samples included in the HHRA are described in Tables 5.1-6 and 5.1-7, respectively. The analytical data set used in the HHRA is included as Appendix A-2, Attachment 2. The groundwater sampling locations included in the HHRA are depicted on Figure 5.1-11.

Screening Results for Site-related Chemicals of Potential Concern and Naturally Occurring Chemicals

The approach and SLs used to select the COPCs (site-related COPCs or naturally occurring chemicals) are described in Section 4.3.1. The results of the COPC screening process for a hypothetical resident potentially exposed to groundwater are provided in Appendix A-2, Attachment 1 (Tables 2.1 and 2.2). The COPCs (site-related COPCs or naturally occurring chemicals) identified in site groundwater are summarized in the tables below.

Summary of COPCs for the EBPs—Site-Related

Receptor	COPC	Frequency of Detections	Minimum Detection (µg/L)	Maximum Detection (µg/L)
Groundwater Used for Tap Water				
Future Hypothetical Resident	4-Amino-2,6-dinitrotoluene	1/22	0.32	0.32
	RDX	8/23	0.31	47
	Barium	14/14	44.9	612
	Cobalt	1/1	3.8	3.8
	TCE	2/20	2	3
Groundwater to Indoor Air via Vapor Intrusion				
Future Hypothetical Resident	TCE	2/20	2	3

Summary of COPCs for the EBPs—Naturally Occurring Chemicals

Receptor	COPC	Frequency of Detections	Minimum Detection (µg/L)	Maximum Detection (µg/L)
Groundwater Used for Tap Water				
Future Hypothetical Resident	Arsenic	10/22	2.5	28
	Cadmium	1/14	0.36	0.36
	Chromium	4/14	0.76	14.9
	Manganese	1/1	84.9	84.9

5.1.6.3 Exposure Assessment

The EBPs is an inactive site, and no buildings are present. Demilitarization by open burning was performed at the EBPs site. The EBPs area is open to recreational activities, and hunting is permitted within the site boundary. There are no perennial surface water features within the EBPs; exposures to Spring Creek surface water and sediment are addressed in the WBPA HHRA. As previously discussed, groundwater is not being used as a potable water source; however, the HHRA for the EBPs evaluated potential exposures to groundwater due to its potential future use as a drinking water source. This consists of the evaluation of future site worker and residential exposures to groundwater. Therefore, ingestion, dermal contact, and inhalation exposures to COPCs in groundwater were estimated for future hypothetical residents (and site workers, if applicable); inhalation exposures of COPCs in indoor air from vapor intrusion of groundwater were also evaluated at the EBPs. Culverts are located at the EBPs; therefore, potential ingestion, dermal contact, and inhalation exposures to shallow groundwater in a trench are complete for future construction/utility workers. As noted previously, risks and hazards for site workers and construction/utility workers are estimated only if the estimated risks or hazards for a hypothetical residential scenario exceed acceptable risk or hazard levels and COCs are identified for a residential scenario. The potential exposure pathways considered in the HHRA are included in Appendix A-2, Attachment 1 (Table 1) and on Figure 5.1-11. The following receptor scenarios were quantified in the HHRA for the EBPs:

- Future hypothetical residents (adult and child).
  - Groundwater (tap water) COPCs—ingestion, dermal contact, and inhalation of volatiles in household air.
  - Groundwater (vapor intrusion) COPCs—inhalation of volatiles in indoor air.

Risks and hazards for site workers and construction/utility workers were not quantified in the HHRA because the estimated risks and hazards for a hypothetical residential scenario did not exceed acceptable risk or hazard levels and COCs were not identified for a residential scenario.

In accordance with USEPA guidance *Determining Groundwater Exposure Point Concentrations, Supplemental Guidance* (USEPA, 2014b), groundwater EPCs are typically calculated based on the data collected in the core of a plume. One RDX plume is present at the EBPs (Figure 5.1-4). Seven monitoring wells (see Table 5.1-7) are located within the core of the plume; 34 groundwater samples are available in the HHRA dataset for the RDX plume. If the maximum detected concentration of a groundwater COPC was not in the subset of wells from the core of the RDX plume, the maximum detected concentration of the COPC in the sitewide groundwater data set was used.

For groundwater, where a sufficient number of samples and detected concentrations are available for COPCs, the UCL on the mean is selected as the EPC. For COPCs where fewer than eight samples or four detects were available, the maximum detected concentrations were selected as the EPCs. For 4-amino-2,6-dinitrotoluene, arsenic, barium, chromium, and TCE, the maximum detected concentrations were located outside of the RDX plume and were used as the EPCs. The groundwater EPCs used to estimate the chemical intakes for groundwater are provided in Appendix A-2, Attachment 1 (Tables 3.1 and 3.2).

The exposure factors used in the intake calculations for receptor scenarios are included in Appendix A-2, Attachment 1 (Tables 4.1 through 4.3). The primary references for the exposure factor values are the standard default exposure factors presented in the HHEM (USEPA, 2014a).

5.1.6.4 Toxicity Assessment

The oral toxicity values (CSFs and RfDs) and inhalation toxicity values (IURs and RfCs) used in the HHRA were obtained from the USEPA standard hierarchy of toxicity value sources (USEPA, 2003), as provided in Section 4.3.1. Noncancer toxicity values for the COPCs identified at the EBPs are provided in Appendix A-2, Attachment 1 (Tables 5.1 and 5.2). Cancer toxicity values for the COPCs are provided in Appendix A-2, Attachment 1 (Tables 6.1 and 6.2).

Two COPCs (chromium and TCE) were identified as acting with a MMOA. The ADAFs and exposure assumptions used to calculate adjusted intakes and exposure concentrations for chromium and TCE are provided in Appendix A-2, Attachment 1 (Table 4 Supplement).

5.1.6.5 Risk Characterization

The risk characterization for the EBPs was completed using a four-step process, as discussed in Section 4.3.1. The results of each step are discussed below.

Step 1: Total Combined Risks and Hazards from Site-related COPCs and Naturally Occurring Chemicals

Step 1 consists of calculating receptor-specific ELCRs and His that include contributions from both site-related COPCs and naturally occurring chemicals. The estimated risks and hazards for a hypothetical residential scenario are summarized below in Table 5.1-8.

Table 5.1-8. Summary of Total Combined Risk and Hazard Estimates for Site-related COPCs and Naturally Occurring Chemicals—IAAP-012G: East Burn Pads Groundwater
Iowa Army Ammunition Plant, Middletown, Iowa

Receptor [a]	ELCR/HI Tables (RME) in Appendix A-2, Attachment 1	Exposure Medium	COPC/Chemical	East Burn Pads		
				EPC [b]	ELCR	HI
Hypothetical Resident (Adult)	7.1 and 9.1	Groundwater (Tap water)	4-Amino-2,6-dinitrotoluene	0.32	NA	0.1

			Total HI (Groundwater—Tap Water):		**1E-03**	**NA**
		Groundwater (Indoor Air—Vapor Intrusion)	Trichloroethene	0.7	3E-08	NA
		Total HI (Groundwater—Tap Water and Indoor Air):			**1E-03**	**NA**

Notes:

[a] ELCRs were estimated for the adult/child aggregate receptor based on lifetime exposure and noncarcinogenic His were estimated separately for adult and child residents.

[b] EPC Units: groundwater (tap water)—µg/L; Groundwater (Indoor Air—Vapor Intrusion)—µg/m³

[c] Chromium was evaluated as hexavalent chromium in the HHRA.

µg/L = microgram per liter

µg/m³ = microgram per cubic meter

COPC = chemical of potential concern

ELCR = excess lifetime cancer risk

EPC = exposure point concentration

HI = hazard index

NA = not applicable

RME = reasonable maximum exposure

Step 2: Risk Characterization of Naturally Occurring Chemicals

Step 2 consists of calculation of receptor-specific ELCRs and His for naturally occurring chemicals. Four COPCs (arsenic, cadmium, chromium, and manganese) were identified as naturally occurring/or not site-related chemicals in site groundwater at the EBPs, as discussed in Section 5.1.4.2. The maximum detected concentrations of arsenic, cadmium, chromium, and manganese were less than their respective BTVs. The estimated risks and hazards for the naturally occurring chemicals in groundwater for a future hypothetical residential scenario are provided below in Table 5.1-9. The naturally occurring chemicals are not used to identify the final COCs for the EBPs and are not discussed further in the HHRA after this step.

Table 5.1-9. Summary of Risk and Hazard Estimates for Naturally Occurring Chemicals— IAAP-012G: East Burn Pads Groundwater
Iowa Army Ammunition Plant, Middletown, Iowa

Receptor [a]	ELCR/HI Tables (RME) in Appendix A-2, Attachment 1	Exposure Medium	Chemical	East Burn Pads

				EPC [b]	ELCR	HI
(Adult/Child Aggregate)			Chromium [c]	14.9	4E-04	NA
			Manganese	84.9	NA	NA
			Total HI (Groundwater—Tap Water):		**1E-03**	**NA**

Notes:

[a] ELCRs were estimated for the adult/child aggregate receptor based on lifetime exposure and noncarcinogenic HIs were estimated separately for adult and child residents.

[b] EPC Units: groundwater (tap water)—µg/L

[c] Chromium was evaluated as hexavalent chromium in the HHRA.

µg/L = microgram per liter

COPC = chemical of potential concern

ELCR = excess lifetime cancer risk

EPC = exposure point concentration

HI = hazard index

NA = not applicable

RME = reasonable maximum exposure

Step 3: Risk Characterization of Site-related COPCs

Step 3 consists of calculating receptor-specific ELCRs and HIs associated with site-related COPCs. Two explosives, two metals, and one VOC were identified as site-related COPCs for groundwater at the EBPs. The estimated risks and hazards for site-related COPCs in groundwater for a hypothetical resident are provided below in Table 5.1-10.

Table 5.1-10. Summary of Risk and Hazard Estimates for Site-Related COPCs—IAAP-012G: East Burn Pads Groundwater

Iowa Army Ammunition Plant, Middletown, Iowa

Receptor [a]	ELCR/HI Tables (RME) in Appendix A-2, Attachment 1	Exposure Medium	COPC	East Burn Pads		
				EPC [b]	ELCR	HI
Hypothetical Resident (Adult)	7.7 and 9.7	Groundwater (Tap water)	4-Amino-2,6-dinitrotoluene	0.32	NA	0.1
			RDX	47	NA	0.4
			Barium	612	NA	0.1
			Cobalt	3.8	NA	0.4
			Trichloroethene	3	NA	0.9
			Total HI (Groundwater—Tap Water):		**NA**	**2**
		Groundwater (Indoor Air—	Trichloroethene	0.7	NA	0.3

Table 5.1-10. Summary of Risk and Hazard Estimates for Site-Related COPCs—IAAP-012G: East Burn Pads Groundwater

Iowa Army Ammunition Plant, Middletown, Iowa

		Vapor Intrusion)				
				Total HI (Groundwater—Tap Water and Indoor Air):	**NA**	**2[c]**
Hypothetical Resident (Child)	7.8 and 9.8	Groundwater (Tap water)	4-Amino-2,6-dinitrotoluene	0.32	NA	0.2
			RDX	47	NA	0.6
			Barium	612	NA	0.2
			Cobalt	3.8	NA	0.6
			Trichloroethene	3	NA	1.1
				Total HI (Groundwater—Tap Water):	**NA**	**3[c]**
		Groundwater (Indoor Air—Vapor Intrusion)	Trichloroethene	0.7	NA	0.3
				Total HI (Groundwater—Tap Water and Indoor Air):	**NA**	**3[c]**
Hypothetical Resident (Adult/Child Aggregate)	7.9 and 9.9	Groundwater (Tap water)	4-Amino-2,6-dinitrotoluene	0.32	NA	NA
			RDX	47	5E-05	NA
			Barium	612	NA	NA
			Cobalt	3.8	NA	NA
			Trichloroethene	3	6E-06	NA
				Total HI (Groundwater—Tap Water):	**5E-05**	**NA**
		Groundwater (Indoor Air—Vapor Intrusion)	Trichloroethene	0.7	3E-08	NA
				Total HI (Groundwater—Tap Water and Indoor Air):	**5E-05**	**NA**

Notes:

[a] ELCRs were estimated for the adult/child aggregate receptor based on lifetime exposure and noncarcinogenic HIs were estimated separately for adult and child residents.

[b] EPC Units: groundwater (tap water)—µg/L; Groundwater (Indoor Air—Vapor Intrusion)—µg/m^3

[c] No target organ HIs exceeded 1.

µg/L = microgram per liter

µg/m^3 = microgram per cubic meter

COPC = chemical of potential concern

ELCR = excess lifetime cancer risk

EPC = exposure point concentration

HI = hazard index

NA = not applicable

RME = reasonable maximum exposure

Step 4: Final COC Determination

The total ELCRs and HIs estimated for groundwater based on a future hypothetical residential scenario (adult and child) did not exceed USEPA's acceptable risk range of 1×10^{-6} to 1×10^{-4} and target organ HI of 1. Therefore, no COCs were identified for groundwater at the EBPs, and the EBPs qualifies for an NFA decision for groundwater based on the results of the HHRA.

5.1.6.6 Uncertainty Analysis

The assumptions used in the HHRAs have inherent uncertainty. The general uncertainties associated with the HHRAs for the sites in this RI report are provided in Section 4.3.1. This section provides additional site-specific uncertainties associated with the HHRA for the EBPs that are not included in Section 4.3.1.

Total chromium was initially identified as a COPC in groundwater because the maximum detected concentration for total chromium exceeded the tap water RSL for hexavalent chromium. It is likely that some or all of the total chromium concentrations are in the trivalent chromium form. All of the groundwater chromium concentrations are less than the tap water RSL for trivalent chromium and the MCL and BTV for total chromium. Using the hexavalent chromium RSL to evaluate total chromium in the COPC selection process was a conservative approach in the HHRA. Total chromium was determined to be naturally occurring in groundwater at the EBPs.

Hazard estimates for 4-amino-2,6-dinitrotoluene could be over- or underestimated because screening RfDs were used in the risk calculations. As stated in the Provisional Peer-Reviewed Toxicity Value (PPRTV) documents for 4-amino-2,6-dinitrotoluene (USEPA, 2020c),

> It is inappropriate to derive a subchronic or chronic provisional RfD for 4-amino-2,6-dinitrotoluene. However, information is available which, although insufficient to support derivation of a provisional toxicity value, under current guidelines, may be of limited use to risk assessors… Users of screening toxicity values in an appendix to a PPRTV assessment should understand that there is considerably more uncertainty associated with the derivation of a supplemental screening toxicity value than for a value presented in the body of the assessment.

Chemicals that were 100 percent not detected in groundwater were not included in the COPC identification process; however, they were evaluated in a separate screening to determine whether elevated nondetected results were present in groundwater. The detailed analysis of the nondetected chemicals at the EBPs is provided in Appendix A-2, Attachment 3. In summary, five explosives (2,4-dinitrotoluene, 2,6-dinitrotoluene, 2-nitrotoluene, 3-nitrotoluene, and nitrobenzene), one metal (thallium), one PAH (naphthalene), 13 SVOCs, and 18 VOCs have DLs and/or RLs exceeding SLs at the EBPs. Although the DLs and/or RLs for these nondetected chemicals are greater than the SLs, based on the adequacy of DLs/RLs and comparison to historically detected chemicals in groundwater at IAAAP, further consideration of nondetected chemicals does not appear warranted in the EBPs HHRA.

5.1.6.7 Summary of HHRA

An HHRA was prepared for the EBPs to evaluate potential current and future health risks from exposure to chemicals in site groundwater. The EBPs is no longer active, and no buildings are present at the site. The site is open to recreational activities and hunting is permitted within the site boundary. However, the hunter/recreator is not evaluated in the HHRA because soil is addressed under OU1 (IAAP-012) (Leidos, 2018), and exposures to surface water and sediment in Spring Creek, which borders the EBPs, are addressed with the WBPA HHRA. No other perennial surface water or sediment is present at the EBPs.

The following potential future human receptors were identified in the HHRA for the EBPs:

- **Future Site Workers.** Future site workers could contact groundwater based on its potential future use as a drinking water source at the EBPs and could be exposed to indoor air (that may be impacted by volatile chemicals migrating from groundwater) in buildings.
- **Future Construction/Utility Workers.** Future construction/utility workers could contact shallow groundwater while replacing a culvert located within the EBPs.
- **Future Hypothetical Residents.** Future hypothetical residents could contact groundwater based on its potential future use as a drinking water source at the EBPs and could be exposed to indoor air (that may be impacted by volatile chemicals migrating from groundwater) in buildings.

Potential exposures and risks and hazards to future site workers and construction/utility workers were not estimated in the HHRA since estimated risks and hazards for a hypothetical residential scenario did not exceed acceptable risk and hazard levels and no COCs were identified for a residential scenario.

The COPCs (site-related COPCs or naturally occurring chemicals) identified in site groundwater are as follows:

- Groundwater (potable use):
  - Naturally occurring: arsenic, cadmium, chromium, and manganese.
  - Site-related: 4-amino-2,6-dinitrotoluene, RDX, barium, cobalt, and TCE.
- Groundwater (vapor intrusion): TCE.

The risk characterization for the EBPs was completed using a four-step process, as discussed in Section 4.3.1. Step 1 presents the total combined risks and hazards from site-related COPCs and naturally occurring chemicals, as summarized in Table 5.1-8. Step 2 presents the risks and hazards from naturally occurring chemicals, as summarized in Table 5.1-9. Step 3 presents the risks and hazards from site-related COPCs, as summarized in Table 5.1-10.

No unacceptable groundwater risks or hazards were identified in Step 3 for hypothetical residents. Therefore, in Step 4, no COCs were identified for groundwater at the EBPs, and the EBPs site qualifies for an NFA decision for groundwater based on the results of the HHRA.

5.1.7 Ecological Risk Assessment

The ERA for groundwater at the EBPs is presented herein, beginning with Step 1 of the ERA process (to determine whether there are complete exposure pathways). Soil at the EBPs is already addressed under the remedy for OU-1. Spring Creek runs just inside the western boundary of the site; surface water and sediment from this feature were evaluated during the watershed ERA (Appendix I). A summary of the ERA conclusions for Spring Creek are provided in the ERA for the WBPA (Section 5.2.7).

Groundwater is present onsite, but ecological receptors are not exposed directly to groundwater; nevertheless, groundwater is a transport medium, and contaminated groundwater has potential to migrate to and discharge to surface water bodies. There are ditches onsite for drainage purposes; these are not perennial water bodies and do not provide suitable habitat for ecological receptors. Furthermore, as previously noted, there is no connectivity between the ditch and groundwater. Other than the small portion of Spring Creek that runs through the EBPs (and is evaluated under the WBPA site), there is a lack of perennial surface water bodies on the EBPs. Therefore, the groundwater-to-surface-water exposure pathway is incomplete. There are no complete exposure pathways for ecological receptors on the site. Therefore, there are no adverse effects identified and no additional actions are required from an ecological perspective.

5.1.8 Conclusions and Recommendations

An RI was conducted for the EBPs to refine the nature and extent of contamination in groundwater from historical activities and assess for potentially unacceptable risk to human health and adverse effects to the environment. Analytical data available for groundwater at EBPs includes data for explosives, VOCs, SVOCs, PAHs, PCBs, pesticides, radionuclides, and metals. Of these, explosives, VOCs, and metals were identified as site-related chemicals of interest based on historical site operations and a comparison of concentration data to site characterization PALs and BTVs (See Section 4.1).

In groundwater, no VOCs or metals were detected above their site characterization PAL or BTV (if available) during the most recent sampling events. Only one explosive (RDX) was detected above its site characterization PAL, and concentrations have been decreasing between 2007 and 2020 at existing monitoring wells at the EBPs, except for EBP-MW4 and EDA-3. RDX groundwater contamination is present as one large plume, which exists primarily within the overburden aquifer. Increasing trends at these monitoring wells EBP-MW4 and EDA-3 may be indicative of some plume migration. However, the overburden aquifer is absent in the western portion of the site, where it pinches out and bedrock outcrops to the surface. Along with the slow groundwater flow velocity, this may be limiting the extent of plume migration. As such, no RDX exceedances have been observed in the most downgradient monitoring wells at the site. The RDX plume is considered to be laterally and vertically delineated.

The soil removal that was completed in 1999 is assumed to have removed the bulk of RDX contamination that could be a source to groundwater. Although initial confirmation sampling showed RDX concentrations above the OU-1 leachability-based RG (1.3 mg/kg) at Pads 1E, 2E, 4E, 5E, 6E, and 8E, an additional 1 to 2 feet of soil was excavated in these areas following the confirmation sampling. Because a second round of confirmation sampling was not conducted, it is unknown whether RDX concentrations in soil still exceeded the leachability goal at the EBPs.

An HHRA and an ERA were conducted to quantify potential risks and hazards to human health and the environment from exposure to contaminants at the EBPs. The following conclusions were made based on the risk assessments:

- The HHRA concluded that there are no unacceptable risks or hazards for hypothetical residents from exposure to groundwater at the EBPs.
- The ERA concluded that there are no adverse effects to ecological receptors identified and no additional actions are required from an ecological perspective.

Based on the results of the RI and risk assessments, NFA is warranted for groundwater at the EBPs. It is recommended that IAAP-012G be transferred to a new OU (OU-10), and NFA be presented as the preferred remedy in a Proposed Plan. In addition, it is recommended that staff gauges EDA-1 through EDA-3 be repaired to obtain accurate groundwater gauging measurements at the site in the future.

5.2 West Burn Pad Area—Groundwater (IAAP-032G)

This subsection summarizes RI activities at the WBPA site within the EDA. This report documents the RI for groundwater, surface water, and sediment at the WBPA (IAAP-032G). Soil at the WBPA is addressed under the remedies for OU-1 and OU-8 (IAAP-032) (Leidos, 2018; USACE and Dawson, 2021; USACE, 2019). Surface water and sediment are evaluated at the WBPA because it is the site within the EDA containing the largest portion of Spring Creek and perennial tributaries within its boundary. Surface water and sediment data from the WBPA were evaluated in the 2022 Watershed ERA (Appendix I) for the Spring Creek watershed, as described in Section 5.2.7.

Munitions and explosives of concern (MEC) and munitions constituents (MC) in soil and groundwater have also been considered under OU-5 (IAAP-003-R-01 and IAAP-005-R-01) (CB&I Federal Services, 2014). Because no MEC or evidence of munitions-related activities were identified at the WBPA, it was concluded that there were no impacts to groundwater from munitions-related activities. The OU-5 ROD documented that NFA is warranted for these two MMRP sites within the WBPA.

5.2.1 Background

5.2.1.1 Site Description

The WBPA composes a generally inactive site located in the northeast portion of the IAAAP facility that covers approximately 14 acres contained within the Spring Creek watershed (Figure 5.1-1). The WBPA is part of a larger area, the EDA.

The WBPA consists of several sites with documented environmental impacts (Figure 5.1-1). Originally, the WBPA (IAAP-032) only included the Burn Cages site. However, the site boundary was later expanded to incorporate the following historical sites: Burn Cage Ash Landfill (IAAP-033), West Burn Pads (WBPs) (IAAP-034), and the WBPs Landfill (IAAP-035). As a result, the IAAP-032 site identification now includes the former Burn Cages site, the Burn Cage Ash Landfill, the WBPs, and the WBPs Landfill. In addition, there are two MMRP (OU-5) sites that fall within the WBPA boundary (IAAP-032): the WBPs MRS (IAAP-003-R-01) and the West Burn Pads South of Road (WBPS) MRS (IAAP-005-R-01). The two MMRP sites have been addressed under the OU-5 ROD (CB&I, 2014).

The WBPA was used for demilitarization by open burning at the burn pads, which were constructed of earthen material, and burn cages, which were constructed of steel. The WBPs consisted of cleared ground with soil berm barriers. The former WBPs were located in the central and southern portions of the WBPA. Former site IAAP-034 consisted of two burn pads (Pad 1-W and Pad 2-W), each approximately 15 by 50 feet. To restrict horizontal movement of projectiles, earthen berms were constructed along three sides of each burn pad, with open access on one side. Burning operations were also performed within metal cages at the Burn Cages site, located immediately east of the Pad 1-W (Figure 5.1-1). The former Burn Cages site consisted of three cages, each measuring approximately 30 by 60 feet (Tetra Tech, 2006).

Ash waste material from the burning operations at WBPs and the Burn Cages site were disposed of at the WBP Landfill and Burn Cage Ash Landfill, respectively. The former WBP Landfill was located in the western portion of the WBPA (Figure 5.1-1) and measured approximately 200 by 300 feet. The former Burn Cage Ash Landfill was located in the eastern portion of the WBPA (Figure 5.1-1) and measured approximately 350 by 125 feet.

Two buildings are present at the WBPA: a wash-down building (BG-13) and an office building (Building 500-183) (Figure 5.1-1). As of July 2012, Building BG-13 remains active and is used to wash down explosives-contaminated equipment (Tetra Tech, 2012). When the WBPA was active, Building 500-183, also referred to as BG-1, was used as a break room for IAAAP employees, but it is now vacant and scheduled for demolition. An underground viewing bunker is still present near Building 500-183.

Additionally, a breached constructed sedimentation dam is present near the WBPA at the convergence of an unnamed tributary with Spring Creek.

5.2.1.2 Operational History

The WBPA was active between 1947 and 1982, with operations that included open burning demilitarization activities, and burning and disposal of dunnage. Open burning was performed on a variety of munitions debris and related materials including explosives-contaminated metals parts and inert and explosives-contaminated packaging. Of note is that lead azide was likely among the materials burned at the WBPA, and liquid Freon was used to reduce the sensitivity of lead azide at the IAAAP. Recoverable metal was segregated for offsite recycling and reuse subsequent to burning. Land disposal was performed at onsite landfills for other wastes from burning operations, including ash, paper, wood, and metal cans.

The Burn Cages site and Burn Cage Ash Landfill operated from 1949 to 1982. The burn cages were used to incinerate inert and explosives-contaminated packaging, and the landfill, where residual ash and residue were placed on the ground and covered with soil, was used for disposal.

The WBPS MRS operated between 1949 and 1982 to flash explosives-contaminated metal parts and store salvageable metal parts. The site was cleared of metal parts in 1997 (Tetra Tech, 2012). The WBPs Landfill operated between 1950 and 1975 and received residue and waste from the WBPs and the EBPs in addition to paper, wood, and metal cans. As with the Burn Cage Ash Landfill, waste material at the WBPs Landfill was placed on the ground surface and covered with soil. The WBPS reportedly contained two trenches used for approximately 1 year in the 1940s or 1950s for flashing of metals contaminated with explosives. An igniter box has been found at the MRS, which indicated the possibility of a former burn pad in the vicinity. The underground viewing bunker that was found near Building 500-183 had a periscope aimed directly at the WBPs (CB&I Federal Services, 2014).

The Atomic Energy Commission conducted activities at the WBPA between 1947 and 1975. In 1975, control of the area reverted to the IAAAP (USACE, 2006). A dam that was observed by USACE during a 2001 field investigation (ECC, 2003) may have been used during Atomic Energy Commission activities. The actual purpose and period of use of the dam is unknown, but it may have been used to impound surface water for treatment prior to discharge to Spring Creek (URS, 2004b). Burning and disposal operations at the WBPA ceased after the Explosive Waste Incinerator was constructed in 1982.

5.2.1.3 Previous Investigations and Remedial Actions

Numerous investigations have been conducted at IAAAP since the 1980s. Table 5.2-1 summarizes the previous investigations and remedial actions conducted at the WBPA, including conclusions and recommendations. Although soil at the WBPA has already been addressed under OU-1, previous investigations for soil are also presented in Table 5.2-1 to support the CSM.

This report summarizes the RI for groundwater, surface water, and sediment at the WBPA (IAAP-032G). Previous investigations pertinent to the RI for groundwater, surface water and sediment are listed below; additional details on these investigations (e.g., including a more detailed description of work completed, as well as work not pertinent to this RI), are included in Table 5.2-1. Previous groundwater, surface water, and sediment sampling locations are shown on Figure 5.1-2.

Investigation	Conclusion
Contamination Survey (ERG, 1982)	Two monitoring wells (G-29 [EBPs] and G-30 [WBPA]) were installed and sampled for explosives. Groundwater samples collected at the WBPA did not contain explosives. Two surface water samples were collected from Spring Creek and analyzed for explosives. No explosives were detected in the samples.

Investigation	Conclusion
Follow-on Study of Environmental Contamination (Battelle, 1984)	Two surface water samples were collected from Spring Creek, upstream and downstream of the EDA, and analyzed for explosives. No contamination was found in surface water at the EDA. No additional recommendations were made for the EDA sites.
Midwest Site Confirmatory Study (Dames and Moore, 1986)	Groundwater samples were collected from the one monitoring well at the WBPA (G-30) and analyzed for explosives, VOCs, and metals. Two surface water samples were collected from Spring Creek, upstream and downstream of the EDA and analyzed for explosives, metals, and VOCs. No explosives or VOCs were detected in groundwater at the WBPA. Copper was detected in several EDA wells, including G-30; however, no other metals were detected at G-30. In surface water, one explosive was detected upstream and metals were detected in both upstream and downstream samples. No VOCs were detected in surface water around the EDA.
RCRA Facility Assessment (Ecology and Environment, 1987)	Three sediment samples were collected from the EDA and analyzed for explosives and metals. Significant levels of explosives (RDX, HMX, 1,3,5-TNB, and TNT) were detected. High metals concentrations were found upgradient and downgradient of the site. Heavy metals concentrations upgradient and downgradient of the open burning pit were high. Additional sediment sampling was recommended.
Facility-wide Preliminary Assessment (JAYCOR, 1994)	The Preliminary Assessment indicated there was a potential for contamination at the WBPA. It was recommended that soil, surface water, and sediment samples should be collected at the WBPA.
Facility-wide Site Inspection (JAYCOR, 1992)	Three sediment samples were collected at the EDA during the SI and were analyzed for explosives, metals, and VOCs. No groundwater samples were collected at the WBPA during the SI. Metals and explosives were detected in sediment at the WBPA. Further investigation was recommended as part of the RI.
Phase I and Follow-on Remedial Investigation (JAYCOR, 1993, 1996)	No groundwater sampling was conducted during the Phase I RI. Four new monitoring wells and one existing monitoring well at the WBPA were sampled for explosives and metals during Phase II. During follow-on work, all monitoring wells were also sampled for VOCs and explosives. In groundwater, explosives and metals were the main contaminants observed at the WBPA, and VOCs were detected during the follow-on sampling. The RI recommended semiannual compliance groundwater monitoring at one wells in the WBPA for VOCs, explosives and metals. Surface water and sediment samples were collected from four locations along Spring Creek (RBW-SW/SD-07, -10, -14, and -16). No explosives, VOCs, or SVOCs were detected in upstream samples or in downstream. Metals were detected at low levels in all samples.
Periodic Groundwater and Surface Water Monitoring (multiple reports)	Periodic groundwater and surface water sampling was conducted at the WBPA between the 1994 and 2007 as part of the FFA compliance monitoring and groundwater monitoring program. However, groundwater samples were collected only until 2004, after which groundwater was removed from the sampling program because of a treatability study. Samples were analyzed for VOCs, SVOC, explosives, metals, radionuclides, and/or natural attenuation parameters. Explosives, primarily RDX, were detected above comparison criteria in shallow monitoring wells and upper bedrock wells at the WBPA. RDX concentrations above 100 µg/L were confined to the southeastern portion of the site.

Investigation	Conclusion
Supplemental Groundwater Remedial Investigation (MWH, 2001)	In 1997, groundwater samples were collected from eleven existing monitoring wells at the EDA and analyzed for VOCs, SVOCs, explosives, and metals. Explosives (RDX, HMX, 1,3-5-TNB, and TNT) and metals (lead, cadmium, and barium) exceeded screening levels at least one of three locations (JAW-23, JAW-24, and JAW-25). The maximum concentration of RDX was detected at bedrock well JAW-23 (6,900 µg/L). No VOCs and SVOCs were detected above screening levels at the WBPA monitoring wells. It was concluded that RDX contamination was present in both shallow overburden wells and bedrock; however, no deeper wells were present in the area to provide vertical delineation.
Additional Monitoring Well Installation (Harza, 2000)	Five new bedrock monitoring wells and two new shallow overburden wells were installed at the WBPA and added to the groundwater monitoring program.
Feasibility Study Data Collection (URS, 2003, 2004b)	Groundwater samples were collected from 21 DPT borings and analyzed for explosives and VOCs. Groundwater samples were also collected from three new bedrock monitoring wells and analyzed for explosives, metals, VOCs, and natural attenuation parameters. Eight surface water samples were collected and analyzed for VOCs, explosives, and metals. VOCs and explosives were detected in DPT groundwater samples. Explosives, VOCs, metals, and nitrate were detected above screening levels at the WBPA. No groundwater contamination was detected in bedrock above the screening criteria. RDX and Freon 113 were selected as the main COPCs in groundwater at the WBPA. Risk assessments were conducted using the groundwater data collected during the Feasibility Study investigation and the groundwater and surface water data collected during the periodic, compliance, monitoring events. Bromodichloromethane, TCE, 2,4-DNT, 2,6-DNT, RDX, and arsenic were identified as groundwater COCs at the WBPA, while there were no COCs identified for surface water. Groundwater flow and contaminant fate and transport models were developed. The models predicted that RDX concentrations in groundwater should continue to decline over time due to naturally occurring processes. The modeling also indicated high RDX concentrations on the north side of the WBPA are impacting Spring Creek and RDX concentrations above 2 µg/L may be impacting the tributary for another 20 to 25 years. The initial natural attenuation concluded that natural attenuation processes may be occurring in the WBPA RDX plume, while wells with Freon 113 appeared to contribute to a more reductive, anaerobic environment.
Comprehensive Watersheds Evaluation and Supplemental Data Collection Work Plan (Tetra Tech, 2006)	The work plan concluded that no groundwater, surface water, or sediment data gaps were present at the EBPs.
Groundwater Treatability Study (Tetra Tech, 2010)	A two-phase groundwater treatability study was conducted at the WBPA to test the efficacy of in situ bioremediation at reducing the highest level of mixed VOC and explosives contamination (Freon-113 and RDX). High-fructose corn syrup solutions were injected into 24 DPT injection points between 2005 and 2008. Two RDX hot spots were targeted, in the northwest and southeast of the WBPA. Ten monitoring wells were monitored during the study. It was concluded the addition of a carbon amendment enhanced the natural degradation process of explosives in groundwater at the WBPA; however, due to the presence of source material at the time of the study, had little impact on the RDX contamination in the southeast hot spot.
OU-5 RI, MMRP (URS, 2011)	Visual survey and surface clearance activities were conducted. Because no MEC or evidence of munitions-related activities were identified at the WBP MRS or the WBPS, sampling for MC in soil and groundwater was not warranted at either of the munition sites under the MMRP.

As part of the previous investigations under OU-1, explosives, VOCs, SVOCs, pesticides, PCBs, and metals were identified as soil COCs for the EDA (ECC 2001). Elevated levels of explosives (mainly RDX) and metals (barium and lead) were identified in soil around former burn pads, burn cages, and the WBP Landfill and Burn Cages Ash Landfill (ECC 2001); the former burns pad and landfill locations are shown on Figure 5.1-1. To address risks and hazards associated with these COCs, soil removal actions have been conducted at the WBPA and LUCs have been implemented (Leidos, 2019); excavation areas are shown on Figure 5.1-1. Soil removals have been conducted under the IRP and FUSRAP.

In 2000 under the IRP, approximately 46,496 cubic yards of contaminated soil were removed from the WBPA. In the excavation areas where the soil was removed down to bedrock, sand backfill and a geotextile fabric were placed on top of the rock. The entire area was backfilled with clean clay fill. Confirmation samples collected in 2000 from excavations indicated that RDX was still present above OU-1 leachability RGs at four of the excavation areas (WBP Landfill, Pad 2-W, Burn Cage Ash Landfill, and Pad 1-W) (Tetra Tech, 2012). No further excavation was required because bedrock was encountered and/or due to the low levels of explosives (ECC, 2001).

Additional excavations were conducted under FUSRAP from 2009 to 2010 to remediate explosives and metals at the WBPS (USACE and Dawson, 2021). During this removal action, an estimated 19,050 cubic yards of contaminated soil was removed from the WBPS. Confirmation samples demonstrated that RGs were met at the WBPS and no additional remedial actions were proposed for soil at the WBPA (USACE and Dawson, 2021). The final inspection was performed at the WBPS in 2012 and all areas were certified as “construction complete.”

During the OU-5 RI, no MEC was recovered at the WBPA, and only one piece of munitions debris was recovered. The OU-5 ROD documented that there is no action necessary to address MEC or MC in soil or groundwater for the MMRP sites, the WBP MRS (IAAP-003-R-01) and the WBPS MRS (IAAP-005-R-01) (CB&I, 2014).

5.2.2 2018–2020 Remedial Investigation Activities

Additional field work was conducted at the WBPA to resolve data gaps needed to complete the RI for groundwater (IAAP-032G). As documented in the final *Site-specific Worksheets for Operable Unit 6 of the Uniform Federal Policy–Quality Assurance Project Plan for Remedial Investigation at Iowa Army Ammunition Plant (Packet 2*) (CH2M, 2018a), explosives, VOCs, and metals in groundwater required further horizontal and vertical delineation, and an improved understanding of current conditions (including groundwater–surface water interactions) was warranted to complete the RI. To address these data gaps, the installation of three overburden monitoring wells and three bedrock monitoring wells was proposed along with groundwater sampling of 26 existing WBPA wells and the newly installed monitoring wells. Groundwater samples were also proposed from four newly installed wells at the EBPs (Section 5.1) and from four existing wells at the NBP (Section 5.3). Five surface water samples were proposed to evaluate surface water contamination upstream and downstream of the EDA. Two staff gauges were also proposed along with two monitoring events (during high-water-level and low-water-level periods) to evaluate whether the tributary and creek was gaining or losing. Fieldwork completed at the WBPA was conducted in accordance with the UFP-QAPP (CH2M, 2018a).

5.2.2.1 2018-2020 Field Activities

Between May 11 and August 2, 2018, three new monitoring wells were installed at the EBPs. The three new bedrock monitoring wells (WBP-MW6, WBP-MW8, WBP-MW9) were installed in 2018 to meet the data quality objectives. Well locations are shown on Figure 5.1-2. Installation of three additional overburden locations (WBP-MW4, WBP-MW5, and WBP-MW7) were attempted; however, locations were dry (that is, groundwater is not present in the overburden in this area of IAAAP), and no wells were installed. A summary of the proposed and newly installed monitoring wells is provided below.

Station ID	Groundwater Unit	Total Depth (Feet bgs)	Screen Interval (Feet bgs)	Rationale
WBP-MW4	Overburden	12.5	Dry, no well installed.	To delineate COPCs north of WBP-DP20.
WBP-MW5	Overburden	5.5	Dry, no well installed.	To delineate RDX south of eastern RDX hot spot.
WBP-MW6	Bedrock	46.5	29–39	To horizontally delineate COPCs at WBP-99-6 to the west.
WBP-MW7	Overburden	6.4	Dry, no well installed.	To horizontally delineate COPCs north of WBP-99-6, WBP-DP05, and WBP-TTMW-05B.
WBP-MW8	Bedrock	42	32–42	To horizontally delineate COPCs to the south of WBP-99-6.
WBP-MW9	Bedrock	82	70–80	To vertically delineate COPCs at WBP-99-6.

New monitoring wells were drilled via rotosonic drilling techniques with a MiniSonic drill rig and 6-inch drill rods (overburden) and wireline (bedrock) or with a Geoprobe 6620DT drill rig with 6- and 8-inch-outer-diameter augers (shallow overburden) in accordance with Section 3.2.3. Boring logs are provided in Appendix C. All proposed overburden monitoring well locations were drilled to bedrock or refusal. Bedrock monitoring well locations were drilled to depths between 42 and 82 feet bgs, which is consistent with the UFP-QAPP (CH2M, 2018a).

As summarized in the table above, groundwater was not present in the overburden at the WBPA, and no proposed overburden monitoring wells could be installed within this aquifer unit. Bedrock monitoring well borings were cored up to 82 feet bgs to look for groundwater presence in the bedrock cores. Based on field observations (such as, fracture frequency and moisture content), the bedrock wells were screened across intervals that were the mostly likely to produce groundwater. Once the screen interval was selected, the borings were reamed with 6-inch drill rods via sonic drilling techniques to the identified monitoring well depth. Well construction details are provided in Table 5.1-2. Bedrock monitoring wells were completed with a 2-inch-nominal-diameter Schedule 40 PVC screen and riser and 0.5-foot Schedule 40 PVC end cap. Bedrock monitoring wells were screened with a machine-slotted, 0.010-inch, 10-foot screen, except for WBP-MW9. Monitoring well WBP-MW9 was completed with a wire-wrapped stainless-steel screen due to its depth (> 80 feet) within the bedrock aquifer. Bedrock fractures decrease with depth at IAAAP and using a wire-wrap screen provides a larger surface area to contact the more limited fractures at depth. Centralizers were installed at the base and just above the screened interval. Monitoring wells were constructed with a certified-clean silica sand filter pack from the base of the borehole to 2 feet above the top of the screen. A 5-foot-thick bentonite layer was placed above the filter pack sand and hydrated, except at WBP-MW6 where a 23-foot-thick bentonite layer was placed. The wells were grouted to the surface, and a steel stickup well protector was installed and surrounded by three bollards. Well completion diagrams are included in Appendix C.

Three staff gauges (Staff Gauge EDA-1 through Staff Gauge EDA-3) were installed on August 18 and 19, 2018, within Spring Creek and its tributaries (Figure 5.1-3). Staff Gauge EDA-1 was installed within the WBPA northern tributary, Staff Gauge EDA-2 was installed within Spring Creek in the central western portion of the WBPA, and Staff Gauge EDA-3 was installed within the NBPLF northern tributary.

On August 20, 2018, newly installed monitoring wells (WBP-MW6, WBP-MW8, and WBP-MW9) were developed as described in Section 3.2.4. Groundwater sampling was attempted at monitoring well WBP-MW6, in March 2019; however, it was noted this location required additional well development. WBP-MW6 was redeveloped on December 19, 2019, and was sampled via low-flow sampling techniques on

May 7, 2020. All monitoring wells were purged dry at least once. All WBPA monitoring wells were considered developed due to the slow recharge. Well development logs are provided in Appendix C.

A sitewide (EDA) groundwater survey was completed on March 3, 2019. Following this sitewide gauging event, groundwater samples were collected from 29 existing and newly installed monitoring wells between March 2019 and May 2020 (Tables 5.1-3 and 5.2-2). Twenty-five existing monitoring wells (G-30, WBP-TTMW-10 through WBP-TTMW-15, JAW-23 through JAW-25, WBP-99-1 through WBP-99-6, and WBP-MW1 through WBP-MW3) and two new monitoring wells (WBP-MW8 and WBP-MW9) were sampled via low-flow purging and sampling techniques between March 3 and 24, 2019. Existing monitoring well JAW-68 was sampled on December 19, 2019. Groundwater samples were collected for explosives by Method SW8330B, VOCs by Method SW8260, and/or RCRA metals by Method SW6020A. Purge logs are included in Appendix C. Data were managed and validated as discussed in Section 3.3. Laboratory reports are provided in Appendix B.

On March 12 and 19, 2019, four surface water samples were collected from Spring Creek and its tributaries at the EDA. Surface water samples EDA-SW04 and EDA-SW02 were collected from Spring Creek, upstream and downstream of the EDA, respectively. Surface water samples collected upstream and downstream of the EDA were analyzed for explosives by Method SW8330B, VOCs by Method SW8260, and total and dissolved Target Analyte List metals by Method SW6020A. One surface water sample, EDA-SW01, was collected from the intermittent tributary along the southern boundary of the WBPA, downgradient of G-30, and one surface water sample, EDA-SW03, was collected downstream of EDA-SW04 and downstream of the NBPLF and were analyzed for explosives by Method SW8330B. A fifth surface water sample was attempted at the intermittent tributary northeast of the NBPLF; however, this tributary was dry and no samples were collected.

All IDW generated during activities (soil and purge water) was disposed of in accordance with management activities discussed in Section 3.2.9. Waste management documentation is provided in Appendix D.

The three newly installed monitoring wells WBP-MW6, WBP-MW8 and WBP-MW9 and the three newly installed Staff Gauges EDA-1 through EDA-3 (3-foot marker) were surveyed by Bruner, Cooper, and Zuck, Inc., licensed Iowa surveyors, on September 24, 2018, in accordance with Section 3.2.7. Survey information is included in Appendix E. Nine existing monitoring wells (WBP-TTMW-01 through WBP-TTMW-04, WBP-TTMW-05B, WBP-TTMW-06, WBP-TTMW-08, WBP-TTMW-10, and WBP-TTMW-11) were resurveyed on December 17, 2019, since top-of-casing elevation data were not available for these wells.

5.2.2.2 Deviations and Follow-on Field Activities (2020)

The final *Site-specific Worksheets for Operable Unit 6 of the Uniform Federal Policy–Quality Assurance Project Plan for Remedial Investigation at Iowa Army Ammunition Plant, Middletown, Iowa* (Packet 1) (CH2M, 2017b) proposed the installation of six new monitoring wells (three overburden wells and three bedrock monitoring wells) to delineate the COPC plumes at the WBPA. However, due to the thinness of the overburden unit in this area of IAAAP and the lack of groundwater in the overburden, proposed overburden monitoring wells were not installed, as detailed in Section 5.2.2.1. This did not impact the results of the RI since the lack of groundwater in the overburden provides the necessary conceptual site model information.

One proposed overburden location (WBP-MW5) was not accessible during the 2018 or 2019 drilling events, as it required a Missouri-style crossing over a tributary in the south of the WBPA. In early 2020, this location was re-assessed, and it was determined that the tributary was dry enough to access with a track-mounted rig. Therefore, WBP-MW5 was attempted on May 11, 2020. This location was drilled via hollow-stem auger drilling techniques using a Geoprobe 8040DT drill rig with 6-inch-outer-diameter augers in accordance with Section 3.2.3. The boring was drilled to refusal at 5.5 feet bgs. The boring log is provided in Appendix C. This location was dry and due to the thin overburden present, the borehole was subsequently abandoned, and no well was installed. This did not impact the results of the RI since the lack of groundwater in the overburden at this location provides the necessary conceptual site model information.

Staff Gauges EDA-1 through EDA-3 could not be located during the 2019 and 2020 activities and likely had been destroyed. This did not impact the results of the RI since previous data can be used to infer that the creek is a gaining surface water body. In addition, surface water sample data can also be used to assess fate and transport of contamination.

5.2.3 Environmental Setting

5.2.3.1 Topography and Surface Water

The topography of the WBPA site ranges from 630 feet to 680 feel amsl and slopes eastward towards Spring Creek and northward toward an unnamed tributary of Spring Creek that defines the northern boundary of the site. In the northeast portion of the WBPA, surface runoff follows topography and flows generally toward Spring Creek and the unnamed tributary along the northern boundary of the WBPA. In the southern portion of the site, surface water is channeled into ditches along the road between the former burn pads and WBPS and discharges to Spring Creek (Figure 5.1-3).

5.2.3.2 Geology and Hydrogeology

The geology of the WBPA consists of unconsolidated overburden overlying limestone and shale bedrock. The unconsolidated overburden consists of loess and glacial till. A clayey silt to silt loess has been observed in some borings in this area up to depths of 3 to 6 feet bgs, overlying the glacial till. The glacial till has been characterized as a silty clay to sandy clay with fine- to medium-grained sand with localized discontinuous sand seams or lenses. Thickness of the overburden generally ranges from 2 to 35 feet; however, overburden soil pinches out near Spring Creek and bedrock is exposed (Tetra Tech, 2012). The overburden is thickest at WBP-99-5, which is located in the north-central portion of the WBPA (Figure 5.1-2). During the recent RI, bedrock was encountered between 5.5 and 12.5 feet bgs in newly drilled locations. The upper bedrock consists of the weathered Warsaw Formation shale and limestone underlain by the more competent Keokuk Limestone.

At new bedrock monitoring wells installed near Spring Creek, the upper bedrock thickness measured approximately 15 to 25 feet and was moderately to highly weathered, contained isolated voids, and rock quality designations ranged between 40 and 80 percent. Below the weathered and fractured bedrock zone, the bedrock becomes more competent; for example, at WBP-MW8, the rock quality designation in the screened interval was up to 100 percent.

Groundwater at the WBPA is divided into two units, overburden and bedrock groundwater. Historically, overburden groundwater occurs at depths ranging from approximately 1.5 to approximately 23 feet bgs, and bedrock groundwater occurs at depths ranging from artesian to 45 feet bgs. During the 2019 RI gauging event, groundwater levels in the overburden ranged from 3 to 28 feet btoc while groundwater levels in bedrock wells ranged from 4 to 31 feet btoc (Table 5.1-3). Based on the most recent groundwater gauging data from March 2019, overburden groundwater flows easterly towards Spring Creek, as shown on Figure 5.1-3. Calculated horizontal hydraulic gradients range between 0.04 and 0.11 ft/ft. Bedrock groundwater flow has been generally towards the east and southeast (Figure 2-3), also towards Spring Creek, with horizontal gradients ranging from 0.003 to 0.02 ft/ft. Based on 2019 groundwater elevations, an upward vertical gradient was observed at the well pair WBP-99-5 and WBP-MW1 (Table 5.1-3).

Hydraulic conductivity values calculated from slug tests in the overburden aquifer range from 0.034 to 2.4 feet per day (feet/day). In the bedrock aquifer, hydraulic conductivities are lower, ranging from 0.00015 to 0.019 feet/day (Tetra Tech, 2012).

5.2.3.3 Groundwater/Surface Water Interaction

Groundwater gauging data as described in the 2012 SRI, suggest that groundwater is discharging to Spring Creek and intermittently into the unnamed tributary (Tetra Tech, 2012). At JAW-23, groundwater elevations suggest the reach of the unnamed tributary in this area is variably gaining and losing (Figure 5.1-3). At WBP-99-5, groundwater elevations suggest that this reach of the unnamed tributary is primarily gaining (Figure 5.1-3). At WBP-99-3, historical groundwater elevations suggested that Spring Creek is a gaining stream in this area. Former well, WBP-99-3 was located approximately 500 feet downstream of the bend in Spring Creek that is located just north of JAW-24.

Between staff gauge installation in 2018 and the 2019 RI gauging event, the three new staff gauges (Staff Gauges EDA-1 through EDA-3) were damaged and accurate measurements could not be recorded during the sitewide gauging event. It is recommended that these staff gauges be repaired to obtain accurate measurements in the future.

5.2.4 Nature and Extent of Contamination

This subsection describes the nature and extent of contamination at the WBPA. Soil contamination has been addressed under OU-1; however, soil is discussed briefly to inform the CSM for potential groundwater contaminants. Spring Creek runs through the eastern portion of the WBPA, and a perennial tributary of Spring Creek is present along the northern boundary of the site.

The source of contamination at the WBPA is attributed to releases to the surface as a result of historical site operations, including open burn operations and flashing of explosives and waste disposal at the WBP landfills. Incomplete combustion of explosives compounds and metals from ash released to soil may have leached into groundwater.

5.2.4.1 Groundwater

Groundwater samples have been collected at the WBPA since 1981. Twenty-nine active monitoring wells are present at the WBPA. Ten wells are screened in the overburden to depths ranging from 6.5 to 35 feet bgs, one well is screened across the overburden bedrock transition (interface) zone from 5 to 10 feet bgs, and 18 wells are screened in bedrock at depths ranging from 10 to 80 feet bgs (Figure 5.1-2). Total well depths are present in Table 5.1-3. Historical groundwater samples were analyzed for VOCs, SVOCs, PAHs, explosives, metals, PCBs, radionuclides, and pesticides. No pesticides or PCBs were detected in historical groundwater samples, and SVOCs have not been detected in groundwater sampled since 1992 at the WBPA. Based on historical site operations and COCs identified in soil, explosives, VOCs, and metals are considered chemicals of interest in groundwater at the WBPA.

Samples were collected from 29 monitoring wells at the WBPA during the most recent RI activities between 2018 and 2020 and analyzed for explosives, VOCs, and/or metals (Figures 5.1-4 and 5.1-5). Three monitoring wells at the NPBs (JAW-12, JAW-13, and JAW-14), one monitoring well at the FTP (JAW-63) and one monitoring well at the EBPs (EBP-MW13) were also sampled for explosives, VOCs, or metals to support data quality objectives. Table 5.2-2 summarizes the chemicals detected in groundwater between 2000 and 2020 sampling events at the WBPA. Summary tables of all the analytical results (including nondetects) from the 2018–2020 RI activities are provided in Appendix G. Summary tables of all historical analytical results from the WBPA are provided in Appendix H.

VOCs

Thirty-eight VOCs have been detected in groundwater at the WBPA since 2000 (Table 5.2-2). However, only 1,1,2-trichlorotrifluoroethane (Freon 113), 1,1-dichloroethane (DCA), 1,1-dichloroethene (DCE), and TCE have exceeded the site characterization PALs since 2000. During the 2018–2020 RI, these four VOCs (Freon 113, 1,1-DCA, 1,1-DCE, and TCE) were detected at eight locations at the WBPA above their site characterization PALs. Freon 113 exceeded its site characterization PAL (10,000 µg/L) most frequently during the 2019 RI at seven locations (Figure 5.1-5). The maximum Freon 113 concentration was detected at WBP-99-6 (180,000 J µg/L).

VOCs are present in three plumes at the WBPA, two in the northern portion of the WBPA and one plume in the eastern portion of the WBPA (Figure 5.1-5). Of note is a large VOC plume that extends into the southeastern corner of the WBPS; however, this plume is associated with the FTP site (IAAP-039) and therefore is discussed in Section 5.5. The three VOC plumes in the WBPA appear to be relatively small and isolated; they are delineated by previous DPT groundwater and monitoring well data and new monitoring well data.

Explosives

Between 2000 and 2020, sixteen explosives were detected at the WBPA (Table 5.2-2). During the most recent RI monitoring event (2018–2020), only RDX, 2,6-DNT, and 1,3-dinitrobenzene exceeded their site characterization PALs at the WBPA. RDX, which exceeded its PAL (2 µg/L) at 15 locations at the WBPA (Table 5.2-2), is the most prevalent explosive detected in groundwater at the WBPA, as shown on Figure 5.1.4. Between 2000 and 2020, RDX concentrations have remained relatively stable at many wells in the WBPA (for example at WBP-99-1 [2.6–5.8 J µg/L], WBP-99-2 [23–74 J µg/L], WBP-TTMW-07R [1,100–5,430 µg/L, excluding one anomalous low result of 352 µg/L in November 2007], and WBP-TTMW-11 [850–3,640 µg/L, excluding one anomalous nondetect result in June 2009]) (Table 5.2-2). Concentrations of RDX have declined at some wells in the north of the WBPA, near the former treatability study (WBP-TTMW-05B), from a maximum of 273 µg/L in April 2007 to nondetect in March 2019; however, concentrations have also increased near this area (WBP-99-4 and JAW-23) between 2007 and 2019. Trend graphs from the WBPA show variable RDX concentrations have been observed between 2000 and 2019 (Figure 5.2-1). Historically, the maximum concentration of RDX has been detected at JAW-23 in 1997 (6,960 µg/L), although concentrations have decreased in recent years at this location to 35 µg/L in 2019 (Figure 5.2-1). During the 2019–2020 RI, the highest concentrations of RDX were detected at WBP-TTMW-11 at 940 µg/L (Table 5.2-2).

RDX is present predominantly in overburden (where groundwater is present) and shallow bedrock within one plume across the WBPA. As previously discussed, the overburden pinches out near Spring Creek, and groundwater is absent from this zone. The shallow RDX plume is delineated laterally to the west by WBP-DP03, WBP-DP04, and WBP-08 (upgradient of the WBPA). The northern plume boundary is delineated by a number of overburden and shallow bedrock monitoring wells (Figure 5.1-4), as well as by WBP-DP01, WBP-DP02, and WBP-DP20 to the north of the Spring Creek unnamed tributary. To the south, WBP-DP10, G-30, and WBP-TTMW-13 provide lateral delineation of the RDX plume. Well pair WBP-MW2/JAW-24 provides northeast delineation; however, directly to the east, the WBPA is delineated by monitoring wells in the EBPs (EBP-MW13 and EBP-MW17).

Within deep bedrock, RDX exceeded its site characterization PAL at in one well, WBP-MW8 (3.2 µg/L), screened 32 to 42 feet bgs in the north-central portion of the RDX plume. However, RDX was not detected in other deep bedrock wells, including WBP-MW3 (screened 40 to 50 feet bgs) or WBP-MW9, south and north of WBP-MW8, respectively. RDX was also not detected in the deep bedrock monitoring well WBP-MW6 near the northern plume boundary. Both WBP-MW6 and WBP-MW9 are screened deeper than WBP-MW8. Therefore, the vertical extent of the RDX plume is adequately delineated for this RI.

Metals

Eighteen metals have been detected in groundwater at the WBPA since 2000; however, only arsenic, barium, cadmium, iron, lead, and manganese have been detected above their site characterization PALs and BTVs. During the most recent 2019–2020 sampling events, only arsenic, iron, and manganese were detected above their respective PALs and BTVs. Arsenic exceeded its PAL (10 µg/L) and BTV (33.3 µg/L) at one location, WBP-99-5, in 2019 (37 µg/L). Iron exceeded its PAL (14,000 µg/L) and BTV (9736 µg/L) at 11 locations, and manganese exceeded its PAL (430) and BTV (580) at 12 locations in 2009. However, these elevated concentrations of iron and manganese are not considered site-related and are attributed to the enhanced reducing conditions created by the treatability study (Tetra Tech, 2010). As described in Table 5.2-1, high-fructose corn syrup was injected in the subsurface to assess the potential for enhanced bioremediation of Freon 113 and RDX in groundwater in 2005/2006 and 2007/2008. Analysis of iron and manganese were included in the 2005 though 2009 performance monitoring events for monitoring wells located within the treatability study boundary to help evaluate whether reducing conditions were being established. The iron and manganese exceedances were observed during these performance monitoring events. Prior to injections, only manganese exceeded its PAL at two locations (JAW-23 and WBP-99-5) in 2004.

Concentrations of some metals may be naturally elevated in the environment, and may not indicate a CERCLA-regulated release. Several metals (such as cadmium, chromium, lead, mercury, selenium, silver, and zinc) were detected below their BTVs during the latest sampling events and are therefore considered to be naturally occurring in groundwater at the WBPA.

5.2.4.2 Sediment and Surface Water

Surface water and sediment samples have been collected along Spring Creek, upstream and downstream of the EDA, and from the unnamed tributary along the northern portion of the WBPA (Figure 5.1-2). Surface water and sediment samples have been historically analyzed for explosives, VOCs, SVOCs, PAHs, PCBs, pesticides, herbicides (surface water only), and metals. SVOCs, PAHs, PCBs, pesticides, and herbicides have not been detected in surface water or sediment at the EDA. Tables 5.2-3 and 5.2-4 summarize the chemicals detected in surface water and sediment, respectively, between 2000 and 2020.

During the 2018 to 2020 RI, five surface water samples were collected from Spring Creek and its tributaries at the EDA and analyzed for explosives. Upstream and downstream surface water samples (EDA-SW04 and EDA-SW02) were also analyzed for metals and VOCs. The following analytes were detected in the 2018 to 2020 RI surface water samples: aluminum, barium, calcium, copper, iron, magnesium, manganese, nickel, potassium, sodium, vanadium, molybdenum, zinc, and Freon 113. Summary tables of all the analytical results (including nondetects) from the 2018–2020 RI activities are provided in Appendix G. Summary tables of all historical analytical results from the WBPA are provided in Appendix H.

VOCs

Ten VOCs have been detected in surface water. However, only one VOC (chlorobenzene) was detected above its site characterization PAL, and only then at one location, SCT2, in 2004 (Table 5.2-3). SCT2 is located downstream of WBP-TTMW-01, along the unnamed tributary to Spring Creek in the northern portion of the WBPA (Figure 5.1-2). Chlorobenzene was not detected in surface water during subsequent sampling events at the EDA. In 2019, only one VOC was detected in surface water. Freon 113 was detected at EDA-SW04, located upstream of the EDA (Figure 5.1-6), at 2.1 J µg/L, orders of magnitude below its PAL (2,050,000 µg/L).

No VOCs were detected in sediment at the EDA (Appendix H).

Explosives

Fifteen explosives have been detected in surface water at the EDA. However, explosives have only been detected above PALs at one surface water location, SCT2, in 2003 and 2004 (Table 5.2-3). RDX exceeded its site characterization PAL in 2003 and five explosive compounds (1,3,5-trinitrobenzene, TNT, 2,6-DNT, 2-amino-4,6-DNT, and 4-amino-2,6-DNT) exceeded their PALs in June of 2004. However, all explosives were below their respective PALs at this location during subsequent sampling events in November 2004 through 2012 (Table 5.2-3). RDX was also not detected in the downstream surface water sample, EDA-SW02, during the 2019 RI sampling event (Figure 5.1-6). There were no other explosives detected in surface water above their site characterization PALs between 2000 and 2020.

No explosives were detected in sediment at the EDA (Appendix H).

Metals

Twenty-two metals have been detected in six surface water samples collected both upstream and downstream of the EDA since 2000. However, only 10 metals (aluminum, arsenic, barium, chromium, iron, lead, manganese, mercury, selenium, and vanadium) have exceeded their respective PALs and BTVs (if available) at nine surface water locations since 2000. The highest concentrations were detected in surface water samples SC08-H, SC09-H, SC13-H, and SCT2. Surface water samples SC08-H, SC09-H, and SC13-H were collected in September 2000; the samples were collected upstream of the EDA (SC13-H), downstream of the EDA (SC09-H), and between the WBPA and the EBPs (SC08-H). Metals concentrations detected in these three samples were within the same order of magnitude upstream of, within, and downstream of the EDA. (Figure 5.2-2). Because the concentrations are similar in both upstream and downstream samples, it is concluded that former EDA operations are not the source of metals in surface water in Spring Creek. Of note, the Roundhouse Transformer Storage Area (IAAP-040/040G) is the only IRP site upstream of the EDA; the only COCs identified in that area were PCBs. At SCT2, located along the unnamed tributary to Spring Creek in the northern portion of the WBPA, eight metals exceeded their PALs and BTVs at SCT2 in one sampling event, in June 2004. However, metals concentrations during this June 2004 sampling event were one to three orders of magnitude higher than in the previous four sampling events at this same location (Table 5.2-3), suggesting that the June 2004 concentrations were an anomaly. Noteworthy is that barium was the only metal detected above its PAL (220 µg/L) and BTV (236 µg/L) in surface water collected downstream of the WBPA during the same sampling event, at SC2 (253 µg/L). However, this concentration was similar to the barium concentration in the upstream sample, at SC5 (240 µg/L), indicating that elevated barium concentrations were not associated with the WBPA.

During the 2019 surface water sampling event, only dissolved aluminum and total manganese exceeded their PAL and BTVs in surface water (Figure 5.2-2). Manganese concentrations ranged from 140 J µg/L (EDA-SW04, upstream) to 170 µg/L (EDA-SW02, downstream). Given manganese concentrations from upstream and downstream surface water samples were within the same order of magnitude and dissolved manganese concentrations did not exceed the BTV, this metal is not considered to be site-related. Dissolved aluminum exceeded its PAL (87 µg/L) and BTV (75 µg/L) at EDA-SW02, downstream of the EDA. Although aluminum exceeded its BTV it is considered unlikely to be site-related given that aluminum did not exceed its BTV in groundwater and was not identified as a soil COC for the WBPA.

Twenty metals were detected in three sediment samples collected both upstream and downstream of the EDA since 2000. However, only manganese exceeded its PAL (460 µg/L) and BTV (2,300 µg/L) at one location, SC13-H, upstream of the EDA (Figure 5.2-2). Therefore, this exceedance is not considered to be site-related. Several metals (such as aluminum, arsenic, beryllium, cadmium, chromium, copper, iron, lead, nickel, selenium, silver, vanadium, and zinc) were detected in sediment at the EDA below their BTVs and are therefore considered to be consistent with background and naturally occurring.

5.2.5 Fate and Transport

This section discusses the fate and transport of site-related chemicals of interest at the WBPA. This includes chemicals that were detected above both their site characterization PAL and BTV (if available) during the last sampling event for which those chemicals were analyzed. In groundwater, the potential site-related chemicals of interest include VOCs (Freon 113, 1,1-DCA, 1,1-DCE, and TCE), explosives (RDX, 2,6-DNT, and 1,3-dinitrobenzene) and metals (arsenic). In surface water, only one potential site-related chemical of interest was identified, dissolved aluminum. No site-related chemicals of interest were identified for sediment. Fate and transport characteristics for these chemicals were described in Section 3.2.

The WBPA was formerly used for demilitarization by open burning and flashing of explosives and for waste disposal within the WBPs Landfill. The EDA is fenced, and the WBPA is largely vegetated. Two buildings are present at the WBPA, Building BG-13 and office Building 500-183, and a road runs through the center of the WBPA connecting to the EBPs (Figure 5.1-1). An underground viewing bunker is present near Building 500-183. The WBPA falls within the Spring Creek watershed (Figure 2-1), and Spring Creek runs along the eastern boundary of the site (Figure 5.1-1). A perennial unnamed tributary is present in the northern portion of the site, and a breached constructed sedimentation dam is present near the convergence of this tributary with Spring Creek. Surface water drainage occurs through the unnamed tributary and a number of intermittent drainage ditches that ultimately discharge to Spring Creek. The groundwater at the WBPA is present in two aquifers, overburden and bedrock groundwater. Groundwater levels measured in the overburden aquifer range from 1.5 to approximately 23 feet bgs while bedrock groundwater levels range from artesian to 45 feet bgs.

The source of contamination at the WBPA is attributed to unintended releases to the surface as a result of historical site operations, including open burn operations and waste disposal operations. Contaminants in groundwater have been transported from the source release areas through advection and dispersion. Groundwater generally flows east towards Spring Creek (Figure 5.1-3). Hydraulic conductivities of the overburden aquifer range from 0.034 to 2.4 feet per day (feet/day). In the bedrock aquifer, conductivities range from 0.00015 to 0.019 feet/day (Tetra Tech, 2012). Vertical migration at the site is also limited by the generally tight clay lithology in the overburden and the lack of fractures within the bedrock with depth.

As discussed in Table 5.2-1, a groundwater treatability study was conducted from 2005 through 2009 in the northwest portion of the RDX plume, near WBP-TTMW-05B and in the southeast portion of the RDX plume, near WBP-99-3, where historically the highest RDX and Freon 113 concentrations had been observed. DPT injections of a high-fructose corn syrup solution were completed around WBP-TTMW-05B in the north and around WBP-99-3 and WBP-TTMW-07R in the south. Following the treatability study, concentrations of RDX in groundwater decreased in the northern portion of the plume; however, inconsistent RDX concentrations were observed in the southeastern portion of the plume. It was concluded that competing terminal electron accepting processes prevented the sustained degradation of RDX in this location. In the northwest treatment zone, RDX concentrations at JAW-23 WBP-TTMW-04, and WBP-TTMW-08 were reduced to nondetect during within one year of injections; however, while the injections were successful directly around the injection site, RDX conditions to the east and west of the site remained largely unimpacted. Additionally, RDX concentrations at JAW-23 rebounded to 23 J µg/L in 2019.

Natural attenuation mechanisms that are potentially active at the WBPA were evaluated. Natural attenuation includes various physical, chemical, or biological processes that under favorable conditions act without human intervention to reduce the mass, toxicity, mobility, volume, or concentration of contaminants in groundwater. A weight-of-evidence approach was used for this evaluation.

- The primary line of evidence that attenuation is occurring at a site is reduction over time in contaminant concentrations or mass, or both.
  - Explosives were detected above their site characterization PALs in 15 overburden and shallow bedrock monitoring wells during the latest sampling event at the WBPA. Concentration trends were evaluated for RDX, which is the most extensive contaminant in groundwater at the WBPA. RDX concentrations in three of these wells (G-30, WBP-TTMW-03, and WBP-99-6) show decreasing trends since the early 2000s (Table 5.2-2). Recently, the highest concentrations of RDX were detected at shallow bedrock monitoring well WBP-TTMW-11 in 2019 (Table 5.2-2). Most RDX concentrations have remained relatively stable at the WBPA (Figure 5.2-1); however,

decreasing trends at WBP-MW2 and JAW-24, both located near the leading edge of the RDX plume, and a number of decreasing trends along the northern edge of the plume, may be indicative of natural attenuation. However, RDX concentrations increased (WBP-99-4 and JAW-23) between 2007 and 2019, which may be indicative of plume migration or rebound following the treatability study injections.

- VOCs were detected above their site characterization PALs in eight overburden and shallow bedrock monitoring wells during the latest sampling event at the WBPA. Freon 113 is the most extensive VOC in groundwater at the WBPA. In general, Freon 113 concentrations have remained stable at the WBPA.
- Arsenic was also identified as a chemical of interest in groundwater. As previously discussed, total arsenic exceeded its PAL (10 µg/L) and BTV (33.3 µg/L) at only one location, WBP-99-5 in 2019 (37 µg/L). Arsenic concentrations have fluctuated above and below the BTV over time in this well (Table 5.2-2).

- Anaerobic daughter products of RDX were detected at Line 2 in 2018. Low levels (< 5 to 36 J µg/L) of MNX, TNX, and DNX were detected at monitoring wells JAW-23, JAW-25, WBP-99-2, WBP-99-6, WBP-TTMW-02, WBP-TTMW-03, WBP-TTMW-06, and WBP-TTMW-11 providing evidence that anaerobic biodegradation of RDX is occurring at the WBPA.
- On the contrary, other than 1,1-DCE, no reductive degradation products of TCE were observed during the 2019 sampling event. However, the presence of 1,1-DCE and 1,1-DCA may be due to degradation of 1,1,1-TCA, which was historically detected in groundwater at the WBPA (Table 5.2-2). During the 2005–2009 treatability study, groundwater samples were analyzed for ethane and ethene. Both of these dissolved gasses were detected at low levels, indicating that the injections likely enhanced biodegradation of the chlorinated VOCs during this time period.
- Water quality parameters can be used to evaluate whether the geochemical conditions are conducive to biodegradation. During the current RI, groundwater was observed to be under generally aerobic and oxidizing conditions, except at five monitoring wells along the northern RDX plume edge (WBP-99-5, WBP-99-6, WBP-MW2, WBP-MW9, and WBP-TTMW-04) and one deep bedrock well in the center of the plume (WBP-MW3). DO concentrations in groundwater at the WBPA ranged from 0.26 to 8.13 mg/L, and ORP values ranged from -110 to +183 mV (Tables 5.1-5). pH values were relatively neutral (between 6 and 7), which is favorable for biological activity.
- Under these geochemical conditions, anaerobic biodegradation of explosives, particularly RDX, and VOCs may be favorable along the northern edge of the plume where more anaerobic conditions have been observed. However, Freon 113 has shown to be persistent in groundwater (U.S. National Library of Medicine, 2015).
- In areas of the site where conditions are more aerobic and oxidizing, RDX and 1,1-DCE degradation is less favorable. However, 1,1-DCA and TCE can degrade via aerobic cometabolism, which may explain the lack of reductive daughter products. Freon 113, 2,6-DNT, and 1,3-dinitrobenzene can also degrade under aerobic conditions, but Freon 113 may be persistent, and 1,3-dinitrobenzene degradation may be slow. In addition, TCE and RDX can degrade by abiotic means.

The physical natural attenuation processes are also likely helping to stabilize the plumes, given the stable extent of the plumes. While the explosives in groundwater have moderate solubility and relatively low sorption potential, it should be retarded somewhat as it sorbs to the clay geology. Freon 113 also has moderate water solubility and a moderately low sorption potential, while other VOCs are characterized by relatively high solubilities and low sorption potential (Table 4.2-1). The minimal thickness of the overburden aquifer in the WBPA may also be a factor that is limiting plume migration. Explosives have limited volatility (Table 4.2-1) and therefore are unlikely to volatilize into soil gas at the water table interface, while the VOCs have a high vapor pressure and may volatilize into soil gas at the interface with the water table.

Arsenic was the only metal to exceed its PAL and BTV in groundwater during the most recent sampling event in 2019. In oxidizing environments, arsenic can be present in a form that is more mobile; however, it will potentially sorb or complex with clays, organic material, iron hydroxides, or manganese oxides, limiting its mobility (ERG, 2005).

Dissolved aluminum was the only metal to exceed its PAL and BTV in surface water downstream of the EDA, during the most recent sampling event, in 2019. In oxidizing environments, aluminum will tend to be in its immobile form, aluminum hydroxide. Aluminum may also potentially sorb or complex with clays, organic material, iron hydroxides, or manganese oxides, limiting its mobility (ERG, 2005).

5.2.6 Human Health Risk Assessment

An HHRA was prepared for the WBPA to evaluate potential current and future health risks and hazards from exposure to chemicals in site groundwater, surface water, and sediment. Soil media is not included in the HHRA as it is not a component of this RI; soil is addressed under the remedies for OU-1 (IAAP-032) (Leidos, 2018). A brief summary of OU-1 soil COCs is provided in Section 5.2.1.3 and historical remedial activities for soil are presented in Table 5.2-1. MEC and MC in soil and groundwater have also been addressed under OU-5 (IAAP-003-R-01 and IAAP-005-R-01); NFA is documented for these sites in the OU-5 ROD (CB&I, 2014).

The HHRA was conducted in accordance with the final UFP-QAPP (CH2M, 2017a), with the exception of some deviations that were agreed to during meetings or correspondence with USACE and USEPA following approval of the final UFP-QAPP. The approach and method used to conduct the HHRA are provided in Section 4.3.1. This section presents the CEM for the WBPA and provides the results of the four-step evaluation process comprising the following:

- Data evaluation.
- Exposure assessment.
- Toxicity assessment.
- Risk characterization.

The results of the HHRA are used to determine if further action is warranted for groundwater, surface water, and sediment at the WBPA.

5.2.6.1 Conceptual Exposure Model

A description of the WBPA, its operational history, previous investigations, and remedial actions are provided in Sections 5.2.1 and 5.2.2. The soil at the WBPA is addressed under the remedy for OU-1 (IAAP-032 and IAAP-005-R-01) (Leidos, 2018; USACE and Dawson, 2021) and was not reevaluated in this HHRA.

The WBPA is largely inactive and was used for demilitarization by open burning at the burn pads, which were constructed of earthen material, and burn cages, which were constructed of steel. The WBPs consisted of cleared ground with soil berm barriers. Two buildings are present at the WBPA: a wash-down building (BG-13) and an office building (Building 500-183) (Figure 5.1-1). Building BG-13 remains active and, as of July 2012, is used to wash down explosives-contaminated equipment (Tetra Tech, 2012). When the WBPA was active, Building 500-183 was used as a break room for IAAAP employees, but it is now vacant and scheduled for demolition. An underground viewing bunker is still present near Building 500-183.

Spring Creek and perennial tributaries are present within the WBPA site boundary. The site is partially open to recreational activities; therefore, hunting is permitted within the site boundary. Culverts are present at the site; therefore, potential groundwater exposures by future construction/utility workers are complete at the WBPA.

Groundwater is not currently being used as a potable water source and there are no plans to use groundwater for potable purposes in the future; however, based on applicable CERCLA policy and guidance, groundwater at the WBPA is classified as Class IIB, a potential source of drinking water (USEPA, 1989). Therefore, the HHRA for the WBPA evaluates potential exposures to groundwater due to its potential future use as a drinking water source. This consists of the evaluation of future residential exposures to groundwater.

The following potential current and future human receptors were identified in the HHRA for the WBPA:

- **Current and Future Hunters/Recreators (Adult and Adolescent).** Current hunters/recreators could be exposed to surface water and sediment in perennial water bodies while hunting and recreating at the WBPA.
- **Current Site Workers.** Current site workers could be exposed to indoor air (that may be impacted by VOCs migrating from groundwater) in Building BG-13.
- **Future Site Workers.** Future site workers could contact groundwater based on potential future use as a drinking water source at the WBPA and could be exposed to indoor air (that may be impacted by VOCs migrating from groundwater) in buildings.
- **Future Construction/Utility Workers.** Future construction/utility workers could contact shallow groundwater while replacing a culvert located within the WBPA site.
- **Future Hypothetical Residents.** Future hypothetical residents could contact groundwater based on potential future use as a drinking water source at the WBPA and could be exposed to indoor air (that may be impacted by VOCs migrating from groundwater) in future buildings.

As discussed in Section 4.3.1, potential exposures and risks and hazards to current and future site workers and future construction/utility workers are estimated in the HHRA only if the estimated risks and hazards for a hypothetical residential scenario exceed acceptable risk levels and COCs are identified for a residential scenario. The human health CEM presenting potential exposure media, exposure points, receptors, and exposure routes is provided in Appendix A-3, Attachment 1 (Table 1), and depicted graphically in Figure 5.2-3.

5.2.6.2 Data Evaluation

Data Used in the HHRA

The analytical data used in the HHRA consist of surface water and sediment samples collected from Spring Creek and its tributaries and groundwater samples collected at the WBPA.

- **Surface Water.** Three historical surface water samples collected in 2012 and three recent surface water samples collected in 2019 were included in the HHRA. The 2012 surface water samples were analyzed for explosives and VOCs; the surface water samples collected in 2019 were analyzed for explosives (all nondetect), metals, PAHs (all nondetect), and VOCs.
- **Sediment.** Spring Creek is a perennial water body. Three historical sediment samples collected in 2000 from the creek were used in the HHRA for the WBPA. The sediment samples were analyzed for metals. As stated in the UFP-QAPP (CH2M, 2017), "Older data (i.e., data collected prior to 2012) may be used in the human health risk assessments if they are still representative of the site (i.e., groundwater flow is slow), chemicals have properties where there would not be a significant reduction in concentrations over time (e.g., metals), or data are conservative for site conditions."

The WBPA is no longer operational, as described in Section 5.2.1. Potential soil sources to groundwater have been remediated, as described in Section 5.2.1.3. Due to a lack of continuing sources, historical concentrations in groundwater are expected to have remained stable or even decreased due to natural attenuation processes. Therefore, the assumptions in the final UFP-QAPP still hold. Samples collected prior to 2012 are considered representative of, or more conservative than, current conditions at the WBPA.

- **Groundwater.** Recent groundwater samples collected in 2019 and 2020 were used in the HHRA for the WBPA. The groundwater samples collected in 2019 were analyzed for explosives, metals, PAHs, and VOCs. The groundwater sample collected in 2020 was analyzed for explosives, PAHs, and VOCs. Thirty-one groundwater samples were used to evaluate potential exposures for both a potable use scenario and the VI pathway. The groundwater samples were not collected at multilevel wells; therefore, a separate data grouping (based on shallow groundwater only) was not used to evaluate the VI pathway. A separate groundwater data grouping was used to evaluate a construction/utility worker scenario, assuming construction/utility workers could be exposed to groundwater encountered at depths up to 10 feet bgs. Fifteen groundwater samples were used to evaluate potential exposures in a trench for a construction/utility worker.

A summary of the number of chemicals analyzed and detected in site media is provided below:

Chemical Group	Number of Chemicals Analyzed	Number of Chemicals Detected
Groundwater		
Explosives	17	11
Metals	8	5
PAHs	1	1
SVOCs	5	0
VOCs	61	27
Sediment		
Explosives	14	0
Metals	23	20
Surface Water		
Explosives	17	2
Metals	24	12
PAHs	1	0
SVOCs	5	0
VOCs	62	2

A description of the data groupings and samples included in the HHRA are provided in Tables 5.2-5 and 5.2-6, respectively. The analytical dataset used in the HHRA is included in Excel format as Appendix A-3, Attachment 2. The groundwater sampling locations included in the HHRA are depicted in Figure 5.1-11.

Screening Results for Site-related Chemicals of Potential Concern and Naturally Occurring Chemicals

The approach and SLs used to select the COPCs (site-related COPCs or naturally occurring chemicals) are described in Section 4.3.1. The results of the COPC screening process for groundwater are provided in

Appendix A-3, Attachment 1 (Tables 2.1 through 2.5). The COPCs (site-related COPCs) identified in site groundwater are summarized in the tables below.

Summary of COPCs for the WBPA—Site-Related

Receptor	COPC	Frequency of Detections	Minimum Detection (µg/L)	Maximum Detection (µg/L)
Surface Water—No COPCs				
Sediment—No COPCs				
Groundwater Used for Tap Water				
Future Site Worker and Future Hypothetical Resident	1,3-Dinitrobenzene	1 / 29	2.8	2.8
	2,6-Dinitrotoluene	2 / 29	0.34	1
	2-Amino-4,6-dinitrotoluene	6 / 29	0.068	0.54
	4-Amino-2,6-dinitrotoluene	9 / 29	0.058	1.1
	HMX	20 / 29	0.55	450
	RDX	17 / 29	0.51	940
	Arsenic	1 / 8	37	37
	Barium	8 / 8	15	960
	Naphthalene	4 / 25	0.27	3.2
	1,1,2-Trichlorotrifluoroethane (Freon 113)	19 / 25	0.84	180000
	1,1-Dichloroethane	5 / 25	0.36	3.5
	1,1-Dichloroethene	8 / 25	0.24	79
	Benzene	4 / 25	0.17	0.47
	Bromomethane	3 / 25	1.3	8.4
	Chloroform	6 / 25	0.16	21
	cis-1,2-Dichloroethene	7 / 25	0.35	57
	Dichlorodifluoromethane	9 / 25	0.33	230
	Ethylbenzene	3 / 25	0.43	1.9
	Trichloroethene	9 / 25	0.17	54
Groundwater to Indoor Air via Vapor Intrusion				
Current and Future Site Worker and Future Hypothetical Resident	1,1,2-Trichlorotrifluoroethane (Freon 113)	19 / 25	0.84	180000
	1,1-Dichloroethene	8 / 25	0.24	79
	Bromomethane	3 / 25	1.3	8.4
	Chloroform	6 / 25	0.16	21
	cis-1,2-Dichloroethene	7 / 25	0.35	57
	Dichlorodifluoromethane	9 / 25	0.33	230

Summary of COPCs for the WBPA—Site-Related

Receptor	COPC	Frequency of Detections	Minimum Detection (µg/L)	Maximum Detection (µg/L)
	Trichloroethene	9 / 25	0.17	54
Shallow Groundwater in a Trench (<10 ft bgs)				
Future Construction / Utility Worker	1,3-Dinitrobenzene	1 / 15	2.8	2.8
	2,6-Dinitrotoluene	1 / 15	1	1
	2-Amino-4,6-dinitrotoluene	2 / 15	0.42	0.51
	4-Amino-2,6-dinitrotoluene	5 / 15	0.11	1.1
	HMX	11 / 15	0.55	450
	RDX	8 / 15	0.51	940
	Barium	5 / 5	15	640
	Naphthalene	1 / 14	0.27	0.27
	1,1,2-Trichlorotrifluoroethane (Freon 113)	11 / 14	0.84	28000
	1,1-Dichloroethane	3 / 14	0.36	3.5
	1,1-Dichloroethene	6 / 14	0.24	29
	Bromomethane	1 / 14	8.4	8.4
	Chloroform	3 / 14	0.16	2.2
	cis-1,2-Dichloroethene	5 / 14	0.35	57
	Dichlorodifluoromethane	8 / 14	0.33	230
	Trichloroethene	6 / 14	0.17	54

Summary of COPCs for the WBPA—Naturally Occurring Chemicals

Receptor	COPC	Frequency of Detections	Minimum Detection (µg/L)	Maximum Detection (µg/L)
Groundwater Used for Tap Water				
Future Site Worker and Future Hypothetical Resident	Cadmium	1/8	0.63	0.63
Shallow Groundwater in a Trench (<10 ft bgs)				
Future Construction / Utility Worker	Cadmium	1/5	0.63	0.63

5.2.6.3 Exposure Assessment

The WBPA is largely inactive; two buildings are present at the site. One building, BG-13, was still active as of 2012 and is used to wash down explosives-contaminated equipment. The second building, Building 500-183, is vacant and scheduled for demolition. A portion of the site is open to recreational activities and hunting is permitted within the site boundary. Spring Creek flows adjacent to several environmental sites within the EDA (Figure 5.1-1). Because the largest portion of Spring Creek and perennial tributaries are present within the WBPA site boundary, risk assessment of surface water and sediment is included with the WBPA site. As previously discussed, groundwater is not currently being used as a potable water source; however, the HHRA for the WBPA evaluated potential exposures to groundwater due to its potential future use as a drinking water source. This consists of the evaluation of future residential exposures to groundwater. Therefore, ingestion and dermal contact exposures to COPCs in groundwater were estimated for future site workers and hypothetical residents. Additionally, inhalation exposures to site groundwater were also evaluated for hypothetical residents, assuming VOCs could be present in household air as a result of showering, bathing, and other household activities. The vapor intrusion pathway is also considered potentially complete for groundwater for the current active building and for future industrial buildings or residences that are constructed at the WBPA; therefore, potential inhalation exposures to indoor air were evaluated for current and future site workers and future hypothetical residents. Culverts are located at the WBPA; therefore, potential ingestion, dermal contact, and inhalation exposures to shallow groundwater in a trench were evaluated for future construction/utility workers. The potential exposure pathways quantified in the HHRA are included in Appendix A-3, Attachment 1 (Table 1), and on Figure 5.2-3. The following receptor scenarios were quantified in the HHRA for the WBP:

- Current Site Worker
  - Groundwater (vapor intrusion) COPCs—inhalation of volatiles in indoor air
- Future Site Worker
  - Groundwater (tap water) COPCs—ingestion and dermal contact
  - Groundwater (vapor intrusion) COPCs—inhalation of volatiles in indoor air
- Future Construction/Utility Worker
  - Shallow groundwater (trench, 0 to 10 feet bgs) COPCs—incidental ingestion, dermal contact and inhalation of volatiles
- Future hypothetical residents (adult and child)
  - Groundwater (tap water) COPCs—ingestion, dermal contact, and inhalation of volatiles in
  - household air
  - Groundwater (vapor intrusion) COPCs—inhalation of volatiles in indoor air

Risks and hazards for site workers and construction/utility workers were quantified in the HHRA because the estimated risks or hazards for a hypothetical residential scenario exceeded acceptable risk or hazard levels and COCs were identified for a residential scenario. Risk and hazards for hunter/recreators were not quantified in the HHRA because no surface water or sediment COPCs were identified.

In accordance with USEPA guidance *Determining Groundwater Exposure Point Concentrations, Supplemental Guidance* (USEPA, 2014b), groundwater EPCs are typically calculated based on the data collected in the core of a plume. One RDX plume (Figure 5.1-4) and three VOC plumes (Figure 5.1-5) are present at the WBPA; no recent samples were collected from one of the VOC plumes.

Monitoring Wells and Number of Samples from Core of WBPA Plumes

	Plume			
	RDX	**West VOC**	**East VOC**	**South VOC**
Sample Count	23	7	5	0
Monitoring Wells	JAW-23 JAW-25 JAW-68 WBP-99-1 WBP-99-2 WBP-99-4 WBP-99-5 WBP-99-6 WBP-MW1 WBP-MW3 WBP-MW6 WBP-MW8 WBP-MW9 WBP-TTMW-01 WBP-TTMW-02 WBP-TTMW-03 WBP-TTMW-05B WBP-TTMW-06 WBP-TTMW-11 WBP-TTMW-12 WBP-TTMW-14 WBP-TTMW-15	JAW-23 WBP-99-6 WBP-MW6 WBP-MW9 WBP-TTMW-05B WBP-TTMW-06 WBP-TTMW-11	WBP-99-5 WBP-MW1 WBP-TTMW-01 WBP-TTMW-02 WBP-TTMW-03	—

The groundwater EPCs calculated for each plume are provided in Appendix A-3, Attachment 1, Table 3.1 (potable use) and Table 3.3 (groundwater in trench/culvert). For the VI pathway, the sitewide data set was used to estimate the EPCs, as provided in Appendix A-3, Attachment 1, Table 3.2. Future receptors were assumed to have potential exposure to groundwater from all plumes/COPCs; therefore, the highest EPC of the three plumes (or sitewide maximum detected concentration for COPCs not associated with a plume) was selected as the final EPC for each COPC. As discussed in Section 4.3.1.3, the UCL concentration was calculated for each COPC where at least eight samples were available and at least four detected concentrations were observed and the UCLs were selected as the EPCs. The maximum detected concentration was selected as the EPC for COPCs when fewer than four detected concentrations or eight samples were available in the groundwater dataset, since a reliable UCL could not be estimated due to the limited number of detected concentrations or samples. The ProUCL output for the COPCs is provided in Appendix A-3, Attachment 3.

The exposure factors used in the intake calculations for receptor scenarios are included in Appendix A-3, Attachment 1 (Tables 4.1 through 4.5). The primary references for the exposure factor values are the standard default exposure factors presented in the HHEM (USEPA, 2014a).

One COPC (TCE) was identified as acting with an MMOA in site media. The ADAFs and exposure assumptions used to calculate adjusted intakes and exposure concentrations for TCE are provided in Appendix A-3, Attachment 1 (Table 4 Supplement).

5.2.6.4 Toxicity Assessment

The oral toxicity values (CSFs and RfDs) and inhalation toxicity values (IURs and RfCs) used in the HHRA were obtained from the USEPA standard hierarchy of toxicity value sources (USEPA, 2003), as provided in Section 4.3.1. Noncancer toxicity values for the COPCs identified at the WBPA are provided in Appendix A-3, Attachment 1 (Tables 5.1 and 5.2). Cancer toxicity values for the COPCs are provided in Appendix A-3, Attachment 1 (Tables 6.1 and 6.2).

5.2.6.5 Risk Characterization

The risk characterization for the WBPA was completed using a four-step process, as discussed in Section 4.3.1. The results of each step are discussed below.

Step 1: Total Combined Risks and Hazards from Site-related COPCs and Naturally Occurring Chemicals

Step 1 consists of calculating receptor-specific ELCRs and His that include contributions from both site-related COPCs and naturally occurring chemicals. No naturally occurring chemicals were identified as COPCs. The estimated risks and hazards for a hypothetical residential scenario are summarized in Step 3 below in Table 5.2-7.

Table 5.2-7. Summary of Total Combined Risk and Hazard Estimates for Site-related COPCs and Naturally Occurring Chemicals— IAAP-032G: West Burn Pad Area Groundwater, IAAP-003-R-01: West Burn Pads, IAAP-005-R-01: West Burn Pads South of Road
Iowa Army Ammunition Plant, Middletown, Iowa

Receptor [a]	ELCR/HI Tables (RME) in Appendix A-2, Attachment 1	Exposure Medium	COPC/Chemical	West Burn Pad Area

			Total ELCR (Groundwater—Tap Water):		**2E-03[h]**	**NA**
	Total ELCR (Groundwater—Indoor Air and Tap Water):				**2E-03[h]**	**NA**

Notes:

[a] ELCRs were estimated for the adult/child aggregate receptor based on lifetime exposure and noncarcinogenic His were estimated separately for adult and child residents.

[b] EPC Units: groundwater (tap water) and shallow groundwater (trench) - µg/L; groundwater (indoor air—vapor intrusion) and shallow groundwater (trench air) - µg/m^3

Step 2: Risk Characterization of Naturally Occurring Chemicals

Step 2 consists of calculation of receptor-specific ELCRs and His for naturally occurring chemicals. One COPC (cadmium) was identified as naturally occurring/or not site-related chemical in site groundwater at the WPBA, as discussed in Section 5.2.4.2. The maximum detected concentration of cadmium was less than its BTV. The estimated risks and hazards for cadmium in groundwater for a future hypothetical residential scenario are provided below in Table 5.2-8. Naturally occurring chemicals are not used to identify the final COCs for the WBPA and are not discussed further in the HHRA after this step.

Table 5.2-8. Summary of Risk and Hazard Estimates for Naturally Occurring Chemicals— IAAP-032G: West Burn Pad Area Groundwater, IAAP-003-R-01: West Burn Pads, IAAP-005-R-01: West Burn Pads South of Road
Iowa Army Ammunition Plant, Middletown, Iowa

Receptor [a]	ELCR/HI Tables (RME) in Appendix A-2, Attachment 1	Exposure Medium	Chemical	East Burn Pads		
				EPC [b]	ELCR	HI
Hypothetical Resident (Adult)	7.4 and 9.4	Groundwater (Tap water)	Cadmium	0.63	NA	0.2
			Total HI (Groundwater—Tap Water):		**NA**	**0.2**
Hypothetical Resident (Child)	7.5 and 9.5	Groundwater (Tap water)	Cadmium	0.63	NA	0.3
			Total HI (Groundwater—Tap Water):		**NA**	**0.3**
Hypothetical Resident (Adult/Child Aggregate)	7.6 and 9.6	Groundwater (Tap water)	Cadmium	0.63	NA	NA
			Total HI (Groundwater—Tap Water):		**NA**	**NA**

Notes:

[a] ELCRs were estimated for the adult/child aggregate receptor based on lifetime exposure and noncarcinogenic His were estimated separately for adult and child residents.

[b] EPC Units: groundwater (tap water)—µg/L

Step 3: Risk Characterization of Site-related COPCs

Step 3 consists of calculating receptor-specific ELCRs and His associated with site-related COPCs. Nineteen COPCs (six explosives, two metals, one SVOC, and 10 VOCs) were identified as site-related COPCs for groundwater at the WBPA. The estimated risks and hazards for site-related COPCs in groundwater for a current site worker, future site worker, future construction/utility worker, and future hypothetical resident are provided in Table 5.2-9.

Table 5.2-9 Summary of Risk and Hazard Estimates for Site-Related COPCs— IAAP-032G: West Burn Pad Area Groundwater, IAAP-003-R-01: West Burn Pads, IAAP-005-R-01: West Burn Pads South of Road

	Total ELCR (Groundwater—Indoor Air and Tap Water):				**2E-03[h]**	**NA**

Notes:

[a] ELCRs were estimated for the adult/child aggregate receptor based on lifetime exposure and noncarcinogenic His were estimated separately for adult and child residents.

[b] EPC Units: groundwater (tap water) and shallow groundwater (trench) - µg/L; groundwater (indoor air—vapor intrusion) and shallow groundwater (trench air) - µg/m^3

[c] The His for whole body (due to Dichlorodifluoromethane) and NOE (due to 1,1,2-Trichlorotrifluoroethane (Freon 113) exceed 1—Appendix A-3, Attachment 1 (see Tables 9.4 and 10.1).

[d] The His for cardiovascular (due to arsenic and TCE), developmental (due to TCE), immune (due to 1,3 Dinitrobenzene, and TCE), nervous (due to RDX), whole body (due to Dichlorodifluoromethane), and NOE (due to 1,1,2-Trichlorotrifluoroethane (Freon 113) exceed 1—Appendix A-3, Attachment 1 (see Tables 9.5 and 10.2).

[e] The ELCR exceeds 1x10^{-4} (due to Chloroform, TCE, 2,6-Dinitrotoluene, RDX, Arsenic, and Naphthalene)—Appendix A-3, Attachment 1 (see Tables 9.5 and 10.2).

[f] The His for cardiovascular (due to TCE), developmental (due to TCE), immune (due to TCE), exceed 1—Appendix A-3, Attachment 1 (see Tables 9.6 and 10.3).

[g] The His for cardiovascular (due to arsenic and TCE), dermal (due to arsenic), developmental (due to TCE), hepatic (due to 1,1-Dichloroethene, 2-Amino-4,6-dinitrotoluene, 4-Amino-2,6-dinitrotoluene, and HMX), immune (due to 1,3 Dinitrobenzene, and TCE), nervous (due to Bromomethane, RDX, 1,1,2-Trichlorotrifluoroethane (Freon 113) and Naphthalene), respiratory (due to Bromomethane and Naphthalene), whole body (due to Dichlorodifluoromethane), and NOE (due to 1,1,2-Trichlorotrifluoroethane (Freon 113) exceed 1—Appendix A-3, Attachment 1 (see Tables 9.7, 9.8, 10.4, and 10.5).

[h] The ELCR exceeds 1x10^{-4} (due to Chloroform, TCE, 2,6-Dinitrotoluene, RDX, Arsenic, Naphthalene, and 1,1-Dichloroethane)—Appendix A-3, Attachment 1 (see Tables 9.9 and 10.6).

RME = reasonable maximum exposure

Step 4: Final COC Determination

For groundwater potable use by future hypothetical residents, the target organ–specific His exceeded USEPA's threshold of 1 and the cumulative ELCR exceeded USEPA's acceptable risk range (1×10^{-6} to 1×10^{-4}) due to the COPCs indicated below:

Hypothetical Resident		
Groundwater Exposure Pathway	**Chemicals Causing Receptor Target Organ HI > 1**	**Chemicals Causing Receptor ELCR > 1 × 10^{-4}**
Potable use	1,3-dinitrobenzene, 2-amino-4,6-dinitrotoluene, 4-amino-2,6-dinitrotoluene, HMX, RDX, arsenic, barium, 1,1,2-trichlorotrifluoroethane (Freon 113), 1,1-dichloroethene, bromomethane, chloroform, cis-1,2-dichloroethene, dichlorodifluoromethane, naphthalene, TCE	2,6-dinitrotoluene, RDX, arsenic, naphthalene, 1,1-dichloroethane, chloroform, TCE
Indoor air (VI)	1,1,2-trichlorotrifluoroethane (Freon 113), 1,1-dichloroethene, bromomethane, dichlorodifluoromethane, TCE	Chloroform, TCE

These chemicals were identified as COCs in groundwater for future hypothetical residents with the exception of one metal (barium) and two VOCs (chloroform and cis-1,2-dichloroethene). Barium and cis-1,2-dichloroethene were detected at concentrations less than their respective MCLs. Concentrations of chloroform, which is a component of total trihalomethanes (bromodichloromethane, bromoform, dibromochloromethane, and chloroform), were below the MCL for total trihalomethanes. Note that chloroform was the only trihalomethane detected in groundwater in 2019–2020. These chemicals were not identified as COCs in groundwater at the WBPA for potable use. However, chloroform was identified as a COC for indoor air (i.e., VI in groundwater).

The federal MCLs for the COCs (potable use) are presented below:

Chemical	Maximum Detected Concentration (µg/L)	MCL (µg/L)	Exceeds MCL?	Groundwater COC for Potable Use Scenario?
1,1,2-Trichlorotrifluoroethane (Freon 113)	180,000	NA	NA	Yes
1,1-Dichloroethane	3.5	NA	NA	Yes
1,1-Dichloroethene	79	7	Yes	Yes
1,3-Dinitrobenzene	2.8	NA	NA	Yes
2,6-Dinitrotoluene	1	NA	NA	Yes
2-Amino-4,6-dinitrotoluene	0.54	NA	NA	Yes
4-Amino-2,6-dinitrotoluene	1.1	NA	NA	Yes
Arsenic	37	10	Yes	Yes
Barium	960	2,000	No	No
Bromomethane	8.4	NA	NA	Yes
Chloroform	21[a]	80[a]	No	No
cis-1,2-Dichloroethene	57	70	No	No
Dichlorodifluoromethane	230	NA	NA	Yes
HMX	450	NA	NA	Yes
Naphthalene	3.2	NA	NA	Yes
RDX	940	NA	NA	Yes

Chemical	Maximum Detected Concentration (µg/L)	MCL (µg/L)	Exceeds MCL?	Groundwater COC for Potable Use Scenario?
TCE	54	5	Yes	Yes

NA = not applicable

[a] The value of 80 µg/L is based on the MCL of total trihalomethanes, which includes the sum of bromodichloromethane, bromoform, dibromochloromethane, and chloroform. The maximum detected concentration for total trihalomethanes at the WBPA is 21 µg/L; chloroform was the only trihalomethane detected in groundwater.

Because COCs were identified for future hypothetical residents, potential exposures and risks and hazards were also estimated for current and future site workers and future construction/utility workers (summarized in Table 5.2-8).

For current and future indoor air (VI of groundwater) and future groundwater (potable use) exposures by site workers, the target organ–specific HIs exceeded USEPA's threshold of 1 and the cumulative ELCR exceeded USEPA's acceptable risk range due to the COPCs indicated below:

Site Workers		
Groundwater Exposure Pathway	**Chemicals Causing Receptor Target Organ HI > 1**	**Chemicals Causing Receptor ELCR > 1 × 10^{-4}**
Potable use	1,3-Dinitrobenzene RDX, arsenic, and TCE	2,6-Dinitrotoluene, RDX, arsenic, chloroform, and TCE
Indoor air (VI)	Dichlorodifluoromethane and 1,1,2-trichlorotrifluoroethane (Freon 113)	Chloroform and TCE

For contact with shallow groundwater by future construction/utility workers, the target organ–specific HIs exceeded USEPA's threshold of 1 and cumulative ELCR exceeded USEPA's acceptable risk range (1 × 10^{-6} to 1 × 10^{-4}) due to the COPCs indicated below:

Construction/Utility Worker		
Groundwater Exposure Pathway	**Chemicals Causing Receptor Target Organ HI > 1**	**Chemicals Causing Receptor ELCR > 1 × 10^{-4}**
Shallow groundwater	TCE	None
Trench air	TCE	None

In summary, the following COCs were identified for groundwater, as presented in Appendix A-3, Attachment 1, tables:

Chemical	Site Workers (Current) (Table 10.1)	Site Workers (Future) (Table 10.2)	Construction/ Utility Workers (Table 10.3)	Hypothetical Residents (Tables 10.4–10.6)
1,1,2-Trichlorotrifluoroethane (Freon 113)	X	X		X
1,1-Dichloroethane				X
1,1-Dichloroethene				X

Chemical	Site Workers (Current) (Table 10.1)	Site Workers (Future) (Table 10.2)	Construction/ Utility Workers (Table 10.3)	Hypothetical Residents (Tables 10.4–10.6)
1,3-Dinitrobenzene		X		X
2,6-Dinitrotoluene		X		X
2-Amino-4,6-dinitrotoluene				X
4-Amino-2,6-dinitrotoluene				X
Arsenic		X		X
Bromomethane				X
Chloroform		X		X
Dichlorodifluoromethane	X	X		X
HMX				X
Naphthalene				X
RDX		X		X
TCE		X	X	X

5.2.6.6 Uncertainty Analysis

The assumptions used in the HHRAs have inherent uncertainty. The general uncertainties associated with the HHRAs for the sites in this RI report are provided in Section 4.3.1. This section provides additional site-specific uncertainties associated with the HHRA for the WBPA that are not included in Section 4.3.1.

The maximum RL of detected chemicals not identified as COPCs in the RAGS Table 2 Series (Appendix A-2, Attachment 1) was compared to their respective RSL. However, chemicals whose RL exceeds the RSL were not identified as COPC. For the WBP, RLs exceeded RSLs for six VOCs (1,2,4-trimethylbenzene, 1,3,5-trimethylbenzene, chloromethane, 1,2-dichloroethene, xylene, m,p-xylene, and o-xylene). Although the RLs for these detected chemicals are greater than the RSLs, based on the frequency of exceedance, probable chemical interference from detected VOCs and comparison to historically detected chemicals in groundwater at IAAAP, further consideration of these detected chemicals does not appear warranted in the WBPA HHRA.

Noncancer hazards exceed USEPA's target HI of 1 for the current site worker scenario for indoor air exposures from VI of COPCs in groundwater. Two COCs were identified for the groundwater VI pathway: Freon 113 (HI = 113) and dichlorodifluoromethane (HI = 6). Several uncertainties associated with VI hazard calculations result in an overestimation of hazard:

- The use of groundwater data to estimate indoor air concentrations may result in overestimation or underestimation of hazard due to the uncertainties in modeling indoor air concentrations from groundwater data and the assumed lack of a vadose zone source which, if present, would also contribute to indoor air concentrations.
- Use of the maximum detected groundwater concentrations as the EPCs likely results in an overestimation of hazards. The VOC plume is located approximately 300 feet north of the currently active Building BG-13 (Figure 5.1-5).

  - Monitoring well WBP-99-2, located approximately 200 feet northeast of BG-13, has a 2019 detection of 20,000 µg/L of Freon 113.
  - Groundwater flow is generally east, towards Spring Creek.
  - Two monitoring wells within 100 feet of BG-13, but south of the building, have concentrations of Freon 113 less than the VISL and nondetected concentrations of dichlorodifluoromethane.
- Use of USEPA's default attenuation factor to calculate the indoor air EPCs for VI from groundwater to indoor air may result in overestimating indoor air concentrations resulting in overly conservative estimates of hazard to building occupants. The default attenuation factor (0.001) incorporated into groundwater screening levels is not based on site-specific subsurface data and does not consider a chemical's soil adsorption characteristics, and reflects reasonable worst-case conditions (i.e., residential structures) and is particularly conservative when used to assess industrial buildings.
- BG-13, which is used as a wash down for explosives-contaminated equipment, is a single-story building that is 28 feet by 48 feet. The building has a concrete foundation and floor (slab on grade), with concrete block wall, and a precast concrete roof. There is no HVAC system in the building; the building is heated by a propane-fueled boiler. The building has a drive-in bay; the rollup door is open when in use and weather is good. A maximum of two operators are in the building, usually one or two times per week but sometimes up to three times per week.
  - Nonhazard estimates are based on an exposure of 250 days per year, 8 hours per day. Because the actual usage of the building is less (approximately 50 to 100 days per year), the hazard estimates are likely overestimated.
  - When the bay rollup door is open, air mixing within the building is increased and indoor air concentrations decreased. The VI calculations used to estimate indoor air concentrations do not take into account increased air mixing, thus overestimating indoor air concentrations and hazards.

Hazard estimates for 2-amino-4,6-dinitrotoluene and 4-amino-2,6-dinitrotoluene could be over- or underestimated because screening RfDs were used in the risk calculations. As stated in the PPRTV documents for 2-amino-4,6-dinitrotoluene and 4-amino-2,6-dinitrotoluene (USEPA, 2020b, 2020c):

> It is inappropriate to derive a subchronic or chronic provisional RfD for [2-amino-4,6-dinitrotoluene or 4-amino-2,6-dinitrotoluene]. However, information is available which, although insufficient to support derivation of a provisional toxicity value, under current guidelines, may be of limited use to risk assessors.… Users of screening toxicity values in an appendix to a PPRTV assessment should understand that there is considerably more uncertainty associated with the derivation of a supplemental screening toxicity value than for a value presented in the body of the assessment.

Chemicals that were 100 percent not detected in surface water, sediment, and groundwater were not included in the COPC identification process; however, they were evaluated in a separate screening to determine if elevated nondetected results were present in surface water, sediment, or groundwater. The analysis of the nondetected chemicals at the WBPA is provided in Appendix A-3, Attachment 4. In summary, one metal (chromium) and one VOC (1,2,3-trichloropropane) have DLs and/or RLs greater than SLs in surface water. Three explosives (2,4-dinitrotoluene, 2-nitrotoluene, and nitrobenzene), one metal (chromium), three SVOCs (1,2,4-trichlorobenzene, 1,4-dichlorobenzene, and hexachlorobutadiene), and 24 VOCs have RLs and/or DLs exceeding SLs in groundwater. Although the DLs and/or RLs for these nondetect chemicals are greater than the SLs, based on the frequency of exceedance, probable chemical interference from detected VOCs and comparison to historically detected chemicals in groundwater at IAAAP, further consideration of nondetect chemicals does not appear warranted in the WBPA HHRA.

5.2.6.7 Summary of HHRA

An HHRA was prepared for the WBPA to evaluate potential current and future health risks from exposure to chemicals in site surface water, sediment, and groundwater. The WBPA is inactive; two buildings are present at the site but only one building, BG-13, is still active and as of 2012 is used to wash down explosives-contaminated equipment. The site is partially open to recreational activities and hunting is permitted within the site boundary. Spring Creek and perennial tributaries are present within the WBPA site boundary.

The following potential human receptors were identified in the HHRA for the WBPA:

- **Current and Future Hunters/Recreators (Adult and Adolescent).** Current hunters/recreators could be exposed to surface water and sediment in perennial water bodies while hunting and recreating at the WBPA.
- **Current Site Workers.** Current site workers could be exposed to indoor air (that may be impacted by VOCs migrating from groundwater) in Building BG-13.
- **Future Site Workers.** Future site workers could contact groundwater based on potential future use as a drinking water source at the WBPA and could be exposed to indoor air (if impacted by VOCs migrating from groundwater) in buildings.
- **Future Construction/Utility Workers.** Future construction/utility workers could contact shallow groundwater while replacing a culvert located within the WBPA site.
- **Future Hypothetical Residents.** Future hypothetical residents could contact groundwater based on potential future use as a drinking water source at the WBPA and could be exposed to indoor air (if impacted by VOCs migrating from groundwater) in future buildings.

Potential exposures and risks and hazards to future site workers and construction/utility workers were estimated in the HHRA since estimated risks and hazards for a hypothetical residential scenario exceed acceptable risk and hazard levels and COCs were identified for a residential scenario.

The COPCs (site-related COPCs or naturally occurring chemicals) identified in site media are as follows:

- Surface Water: None.
- Sediment: None.
- Groundwater (potable use):
  - Naturally occurring: cadmium.
  - Site-related: 1,3-dinitrobenzene, 2,6-dinitrotoluene, 2-amino-4,6-dinitrotoluene, 4-amino-2,6-dinitrotoluene, HMX, RDX, arsenic, barium, naphthalene, 1,1,2-trichlorotrifluoroethane (Freon 113), 1,1-dichloroethane, 1,1-dichloroethene, benzene, bromomethane, chloroform, cis-1,2-dichloroethene, dichlorodifluoromethane, ethylbenzene, and TCE.
- Groundwater (vapor intrusion): 1,1,2-trichlorotrifluoroethane (Freon 113), 1,1-dichloroethene, bromomethane, chloroform, cis-1,2-dichloroethene, dichlorodifluoromethane, and TCE.
- Groundwater (trench scenario):
  - Naturally occurring: cadmium.
  - Site-related: 1,3-dinitrobenzene, 2,6-dinitrotoluene, 2-amino-4,6-dinitrotoluene, 4-amino-2,6-dinitrotoluene, HMX, RDX, barium, naphthalene, 1,1,2-trichlorotrifluoroethane (Freon 113), 1,1-dichloroethane, 1,1-dichloroethene, bromomethane, chloroform, cis-1,2-dichloroethene, dichlorodifluoromethane, and TCE.

The risk characterization for the WBPA was completed using a four-step process, as discussed in Section 4.3.1. Step 1 presents the total combined risks and hazards from site-related COPCs and naturally occurring chemicals, as summarized in Table 5.2-7. Step 2 presents the risks and hazards from naturally occurring chemicals, as summarized in Table 5.2-8. Step 3 presents the risks and hazards from site-related COPCs, as summarized in Table 5.2-9.

Unacceptable groundwater risks and hazards were identified in Step 3 for hypothetical residents, and in Step 4, six explosives, one metal, one SVOC, and seven VOCs were identified as COCs for future hypothetical residents. Therefore, groundwater risks and hazards were also estimated for current and future site workers and future construction/utility workers. For current site workers, two VOCs were identified as COCs; for future site workers, three explosives, one metal, and three VOCs were identified as COCs; for future construction/utility workers, one VOC was identified as a COC.

In summary, the following COCs were identified for groundwater:

Current Site Worker	Future Site Worker	Future Construction / Utility Worker	Future Hypothetical Resident
1,1,2-Trichlorotrifluoroethane (Freon 113) Dichlorodifluoromethane	1,1,2-Trichlorotrifluoroethane (Freon 113) 1,3-Dinitrobenzene 2,6-Dinitrotoluene Arsenic Chloroform Dichlorodifluoromethane RDX TCE	TCE	1,1,2-Trichlorotrifluoroethane (Freon 113) 1,1-Dichloroethane 1,1-Dichloroethene 1,3-Dinitrobenzene 2,6-Dinitrotoluene 2-Amino-4,6-dinitrotoluene 4-Amino-2,6-dinitrotoluene Arsenic Bromomethane Chloroform Dichlorodifluoromethane HMX Naphthalene RDX TCE

5.2.7 Ecological Risk Assessment

The ERA for the WBPA is presented herein, beginning with Step 1 of the ERA process (to determine whether there are complete exposure pathways). Soil at the WBPA is already addressed under the remedy for OU-1. Due to the presence of Spring Creek, surface water and sediment show complete exposure pathways. Based on the available habitat, the following exposure pathways are potentially complete:

- Ingestion of biota exposed to surface water or sediment.
- Ingestion of surface water or sediment.
- Dermal contact with surface water or sediment.

However, dermal contact, although a potentially complete pathway, is considered a minor exposure; it is critical to the risk assessment only in specialized cases, such as burrowing receptors, which are not modeled for OU-10.

Groundwater is present onsite, but ecological receptors are not exposed directly to groundwater. However, groundwater is a transport medium, and contaminated groundwater has the potential to migrate to and discharge to surface water bodies. In this ERA, groundwater was not evaluated as a potential transport medium for WBPA-related chemicals to a seep, as there is no significant contamination observed in surface water and sediment samples. The ECEM is presented in Figure 5.2-4.

Surface water and sediment data were evaluated in the 2022 Watershed ERA (Appendix I) for the Spring Creek watershed. From the SLERA, copper and silver in sediment were identified as COPECs; these COPECs were carried forward into the BERA. No chemicals were identified as COPECs in surface water. Following the weight-of-evidence evaluation, no COPECs were identified for Spring Creek. The recommendation of NFA for the Spring Creek watershed based on the results of the Watershed ERA (Appendix I) means that no ecological impacts are expected at the WBPA.

5.2.8 Conclusions and Recommendations

An RI was conducted for the WBPA to refine the nature and extent of contamination in groundwater, surface water, and sediment from historical activities and assess for potentially unacceptable risk to human health and adverse effects to the environment. Analytical data available for groundwater at WBPA includes explosives, VOCs, SVOCs, PAHs, PCBs, pesticides, herbicides, radionuclides, and metals. Analytical data available for surface water and sediment collected form perennial features includes explosives, VOCs, SVOCs, PAHs, PCBs, pesticides, herbicides (surface water only), and metals. In groundwater, only explosives, VOCs, and metals were identified as site-related chemicals of interest based on historical site operations and a comparison of concentration data to site characterization PALs and BTVs. In surface water, only dissolved aluminum was identified as a site-related chemical of interest. No site-related chemicals of interest were identified for sediment (See Section 4.1).

In groundwater, three explosives (RDX, 2,6-DNT, and 1,3-dinitrobenzene), four VOCs (Freon 113, 1,1-dichloroethane, 1,1-DCE, and TCE) and one metal (arsenic) were detected above their respective site characterization PALs or BTVs (if available) during the most recent sampling events. RDX groundwater contamination is present as one large plume, which exists primarily within the overburden and shallow bedrock aquifers. Stable and decreasing RDX concentrations are present to the north and east of the RDX plume; however, some increasing trends may be indicative of some plume migration or rebound following the treatability study injections. However, the slow groundwater flow velocity should be limiting the extent of plume migration. As such, no RDX exceedances have been observed in the most downgradient monitoring wells at the site and no explosives contamination was detected in surface water samples downstream of the WBPA. The RDX plume is considered to be laterally and vertically delineated.

In surface water, only dissolved aluminum was detected above its site characterization PAL and BTV in 2019, downstream of the EDA. Dissolved aluminum was not detected upstream of the EDA in 2019.

The soil removals that were completed in 2001 and between 2008 and 2012 are assumed to have removed the bulk of RDX contamination that could be a source to groundwater. However, confirmation samples collected in 2000 from the four excavation areas (WBP Landfill, Pad 2-W, Burn Cage Ash Landfill, and Pad 1-W) indicated that RDX was still present above OU-1 leachability RGs (ECC, 2001), which could be a continuing source at the WBPA. An HHRA and an ERA were conducted to quantify potential risks and hazards to human health and the environment from exposure to contaminants at the WBPA. The following conclusions were made based on the risk assessments:

- The HHRA concluded that there are no unacceptable risks or hazards for hypothetical residents from exposure to surface water or sediment at the WBPA.
- The HHRA identified potentially unacceptable risks and hazards for the following receptors from exposure to groundwater at the WBPA:

Site Receptor	Chemicals (COCs)
Site Workers (Current)	Freon 113, dichlorodifluoromethane
Site Workers (Future)	Freon 113, 1,3-dinitrobenzene, 2,6-dinitrotoluene, arsenic, chloroform, dichlorodifluoromethane, RDX, TCE
Construction/Utility Workers	TCE
Hypothetical Residents	Freon 113, 1,1-dichloroethane, 1,1-dichloroethene, 1,3-dinitrobenzene, 2,6-dinitrotoluene, 2-amino-4,6-dinitrotoluene, 4-amino-2,6-dinitrotoluene, arsenic, bromomethane, chloroform, dichlorodifluoromethane, HMX, naphthalene, RDX, and TCE

- The ERA concluded that no adverse effects to ecological receptors exist at the WBPA. The Watershed ERA (Appendix I) did not identify any COPECs for Spring Creek.

Based on the results of the RI and risk assessments, additional action is warranted to mitigate potentially unacceptable risks to future receptors from site-related COCs in groundwater (Freon 113, 1,1-dichloroethane, 1,1-DCE, 1,1-DCA, 1,3-dinitrobenzene, 2,6-DNT, 2-amino-4,6-dinitrotoluene, 4-amino-2,6-dinitrotoluene, arsenic, bromomethane, chloroform, dichlorodifluoromethane, HMX, naphthalene, RDX, and TCE). It is recommended that an FS be completed under OU-10 to evaluate remedial alternatives to address the unacceptable risks in groundwater at the WBPA (IAAP-032G). It is recommended that TCE reductive degradation products (such as cis-1,2-DCE and vinyl chloride) be included in the monitoring plans of the FS remedial alternatives. NFA is warranted for surface water and sediment. When developing remedial alternatives, the FS should consider the reasonably foreseeable future land use for this area. In addition, it is recommended that staff gauges EDA-1 through EDA-3 be repaired to obtain accurate groundwater gauging measurements at the site in the future.

5.3 North Burn Pads—Groundwater (IAAP-036G)

This subsection summarizes RI activities at the NBPs site within the EDA. This report documents the RI for groundwater at the NBPs (IAAP-036G). Soil is addressed under the remedy for OU-1 (IAAP-036) (Leidos, 2018). A small reach of an unnamed perennial tributary of Spring Creek flows inside the southwestern boundary of the NBP into the WBPA. Spring Creek flows adjacent to several environmental sites within the EDA (Figure 5.1-1). Surface water and sediment are evaluated at the WBPA (IAAP-032G) (Section 5.2) because it is the site within the EDA containing the largest portion of Spring Creek and perennial tributaries within its boundary. A limited discussion of surface water and sediment within Spring Creek is included in this section to support the CSM for the NBPs.

5.3.1 Background

5.3.1.1 Site Description

The NBPs is an inactive site located in the northeast portion of the IAAAP facility that covers approximately 4 acres within the Spring Creek watershed (Figure 5.1-1). The NBPs are part of a larger area, the EDA.

The NBPs area was used for demilitarization by open burning. The site is fenced and there are no remaining structures onsite. The NBPs previously contained two earthen burning pads designated Pad 1-N (north) and Pad 2-N (south) (Figure 5.1-1). Each burn pad was approximately 20 feet by 50 feet. A former 275-gallon diesel fuel refueling station was present at the base of Pad 2-N. The station consisted of an aboveground storage tank without secondary containment that was used to fuel equipment operating in the EDA. The aboveground diesel storage tank replaced a former underground storage tank, which had been north of former Building 199-2 and was removed in 1991.

5.3.1.2 Operational History

The NBPs were active between 1968 and 1972. Operations at the NBPs consisted of open burning of lead azide and gun powder. Of note is that liquid Freon was used to reduce the sensitivity of lead azide at the IAAAP. The resulting ash residue, as well as flashed cans, containers, and construction debris, was disposed at the NBPLF (see Section 5.4). Historical documents indicate that the Atomic Energy Commission operated in the EDA until 1975 (USACE, 2001); however, the NBPs were not impacted by radiological contamination (USACE, 2008).

Historical documents do not indicate that liquid fuel accelerants were used as part of open burning operations. However, diesel fuel was stored and dispensed onsite (JAYCOR, 1996).

5.3.1.3 Previous Investigations and Remedial Actions

Numerous investigations have been conducted at IAAAP since the 1980s. Table 5.3-1 summarizes the previous investigations and remedial actions conducted at the NBPs, including conclusions and recommendations. Although soil at the NBPs has already been addressed under OU-1, previous investigations for soil are also presented in Table 5.3-1 to support the CSM.

This report summarizes the RI for groundwater at the NBPs (IAAP-036G). Previous investigations pertinent to the RI for groundwater are listed below; additional details on these investigations (including a more detailed description of work completed, as well as work not pertinent to this RI), are included in Table 5.3-1. Previous groundwater sampling locations are shown on Figure 5.1-2.

Investigation	Conclusion
Follow-on Study of Environmental Contamination (Battelle, 1984)	Two surface water samples were collected from Spring Creek upstream and downstream of the EDA and analyzed for explosives. No contamination was found in surface water at the EDA. No additional recommendations were made for the EDA sites.
RCRA Facility Assessment (Ecology and Environment, 1987)	Three sediment samples were collected from the EDA and analyzed for explosives and metals. Significant levels of explosives (RDX, HMX, 1,3,5-TNB, and TNT) were detected. High metals concentrations were found upgradient and downgradient of the site. Heavy metals concentrations upgradient and downgradient of the open burning pit were high. Additional sediment sampling was recommended.
Facility-wide Preliminary Assessment (JAYCOR, 1994)	The Preliminary Assessment indicated there was a potential for contamination at the NBPs, however no specific contamination study had been performed in this area. It was concluded that the overall exposure potential resulting from historical burning activities was low at the NBPs.
Facility-wide Site Inspection (JAYCOR, 1992)	No groundwater samples were collected at the NBPs during the SI. Further investigation was recommended as part of the RI.
Phase I and Follow-on Remedial Investigation (JAYCOR, 1993, 1996)	Four new monitoring wells (JAW-11 through JAW-14) were installed and sampled for metals, explosives, and VOCs. In groundwater, metals and low levels of explosives were the main contaminants observed at the NBPs. No VOCs were detected at the NBPs. The RI recommended semiannual compliance groundwater monitoring at two wells in the NBPs for metals. Surface water and sediment samples were collected from the Spring Creek tributary (RBW-SW/SD-15) south of the NBPs during the RI and analyzed for explosives and metals. High levels of explosives and metals were detected in the tributary samples; however, explosives contaminants were possibly due to surface water runoff from the WBPA since no explosives were detected in soil samples from the NBPs.
Periodic Groundwater and Surface Water Monitoring (multiple reports)	Periodic groundwater and surface water sampling was conducted at the NBPs between 1994 and 2003 as part of the FFA compliance monitoring and groundwater monitoring program. Samples were analyzed for explosives, metals, and/or gross alpha and gross beta parameters. In groundwater between 1994 and 2003, low levels of metals, explosives, and VOCs were detected at NBP wells. Between 2000 and 2003, detections of metals and VOCs were below screening levels. RDX was the only explosive detected above comparison criteria at the NBP. In surface water, RDX was not detected after June 2002. Freon 113 concentrations, which were likely from the WBPA, decreased over the periodic monitoring period.
Supplemental Groundwater Remedial Investigation (MWH, 2001)	Groundwater samples were collected from three existing monitoring wells (JAW-12 through JAW-14) and analyzed for VOCs, SVOCs, explosives, and metals. No contaminants were detected at the NBPs above screening levels.
Baseline Ecological Risk Assessment Sampling (MWH, 2004)	Sediment and surface water samples were collected as part of the BERA and analyzed for metals, explosives, SVOCs, pesticides/PCBs, and herbicides. One surface water and one sediment sample (SC13-H) were collected upstream of the NBPs, one surface water and one sediment sample (SC08-H) were collected near the NBPs, and three surface water and three sediment samples were collected downstream of the EDA (SC09-H, SC10-H, SC11-H). Surface water samples SC13-H and SC08-H had RDX concentrations above screening levels in 2000. No explosives were detected in sediment samples.
Comprehensive Watersheds Evaluation and Supplemental Data Collection Work Plan (Tetra Tech, 2006)	The work plan concluded that no groundwater, surface water, or sediment data gaps were present at the NBPs.

As part of the previous investigations under OU-1, explosives, VOCs, SVOCs, pesticides, PCBs, and metals were identified as soil COCs for the EDA (ECC, 2000). Elevated levels of metals and explosives were identified in soil around former burn pads (ECC, 2000); the former burn pad locations are shown on Figure 5.1-1. To address risks and hazards associated with these COCs, soil removal actions have been conducted at NBPs, and LUCs have been implemented (Leidos, 2019); excavation areas are shown on Figure 5.1-1. Approximately 2,990 cubic yards of contaminated soil was removed from excavations around the two burn pads. Confirmation samples verified that all soil COCs were removed to OU-1 remedial goals, with the exception of RDX. RDX exceeded its leachability remedial goal in one confirmation sample from Pad 1-N at 2.7 mg/kg. The USEPA and USACE approved the backfilling of these excavation areas given that additional removal had been conducted, contaminant concentrations were low, the remaining contamination was deep in the soil profile and would be covered with clean soil, human health and ecological risk would be minimal at the site, and removal of additional soil considering the contaminant depth and low risk potential was not cost-effective (USACE, 2016). Therefore, these areas are not expected to be an ongoing source of RDX to groundwater.

5.3.2 2018–2020 Remedial Investigation Activities

Additional field work was conducted at the NBPs to resolve data gaps needed to complete the RI for groundwater (IAAP-036G). As documented in the final *Site-specific Worksheets for Operable Unit 6 of the Uniform Federal Policy–Quality Assurance Project Plan for Remedial Investigation at Iowa Army Ammunition Plant (Packet 2*) (CH2M, 2018a), further investigation was warranted to evaluate whether soil contamination around Pad 1-N, where RDX was left in place at a concentration slightly above its OU-1 RG, had impacted groundwater. Furthermore, an improved understanding of current conditions was warranted to complete the RI. To address these data gaps, the installation of one overburden monitoring well was proposed along with groundwater sampling of four existing wells and the newly installed monitoring well. Fieldwork completed at the NBPs was conducted in accordance with the UFP-QAPP (CH2M, 2017a).

Surface water monitoring of Spring Creek was also warranted to assess potential groundwater–surface water interactions (CH2M, 2018a). This field work was conducted under the WBPA investigation and is discussed in Section 5.2.

5.3.2.1 2018–2019 Field Activities

On June 7, 2018, one new overburden monitoring well (NBP-MW1) was installed at the NBPs to meet the data quality objectives (Figure 5.1-2). NBP-MW1 was installed to evaluate whether groundwater had been impacted within the soil removal area at Pad 1-N.

The new monitoring well was drilled with a Geoprobe 6620DT drill rig with 8-inch-outer-diameter augers in accordance with the methods in Section 3.2.3. The boring log is provided in Appendix C. In accordance with the UFP-QAPP, the overburden monitoring well (NBP-MW1) was screened across the perceived water table, from 15 to 25 feet bgs. Well construction details are provided in Table 5.1-2. NBP-MW1 was completed with a 2-inch-nominal-diameter Schedule 40 PVC screen and riser and 0.5-foot Schedule 40 PVC end cap. The monitoring well was screened with a machine-slotted, 0.010-inch, 10-foot screen. The monitoring well was constructed with a certified-clean silica sand filter pack from the base of the borehole to 2 feet above the top of the screen. A 3.5-foot-thick bentonite layer was placed above the filter pack sand and hydrated. The well was grouted to the surface, and a steel stickup well protector was installed and surrounded by three bollards. The well completion diagram is included in Appendix C.

On June 22, 2018, newly installed monitoring well NBP-MW1 was developed as described in Section 3.2.4. NBP-MW1 was purged dry at least once, and approximately six well casing volumes were purged during development. Monitoring well NBP-MW1 was considered developed due to the slow recharge. The well development log is provided in Appendix C.

Groundwater samples were collected from four existing monitoring wells (JAW-11 through JAW-14) and the newly installed one (NBP-MW1) on March 24, 2019. NBP monitoring wells were sampled via low-flow purging and sampling techniques and analyzed for explosives by Method SW8330B. Groundwater samples from JAW-13 were also collected for VOCs by Method SW8260 to support VOC delineation at the WBPA (discussed further in Section 5.2). Purge logs are included in Appendix C. Data were managed and validated as discussed in Section 3.3. Laboratory reports are provided in Appendix B.

All IDW generated during activities (soil and purge water) was disposed of in accordance with management activities discussed in Section 3.2.9. Waste management documentation is provided in Appendix D.

Newly installed monitoring well NBP-MW1 was surveyed by Bruner, Cooper, and Zuck, Inc., licensed Iowa surveyors, on September 24, 2018, in accordance with the methods described in Section 3.2.7. Survey information is included in Appendix E.

5.3.3 Environmental Setting

5.3.3.1 Topography and Surface Water

The topography at the NBPs slopes to the south towards a tributary of Spring Creek. Surface runoff near the NBPs discharges into a tributary of Spring Creek south of Pad 2-N (Figure 5.1-1). This perennial tributary flows east through the WBPA toward Spring Creek.

5.3.3.2 Geology and Hydrogeology

The overburden geology of the NBP area consists of thin and discontinuous loess overlying till. The loess material is typically silty and less than 2 feet thick and was not observed at newly installed well NBP-MW1. The till is primarily sandy clay containing discontinuous localized sand lenses. The overburden overlies the bedrock of the Warsaw Formation. The bedrock is composed of shale and limestone encountered at depths ranging from 19 to below 25 feet bgs near the NBPs. Bedrock was not encountered during drilling at NBP-MW1 to 25 feet bgs.

Groundwater in the overburden is generally encountered between 3 and 22 feet bgs, with the shallowest measurements recorded in the northeastern portions of the NBP area. During the 2019 EDA-wide gauging event, groundwater was measured between 7 and 19 feet bgs (Table 5.1-3). Based on recent and historical groundwater gauging, overburden groundwater flows to the southeast towards Spring Creek and the tributary to Spring Creek (Figure 5.1-3). Hydraulic gradients range from 0.038 to 0.091 ft/ft. Hydraulic conductivity values were calculated from slug tests and range from 0.0015 to 8.6 ft/day in the overburden (Tetra Tech, 2012).

5.3.4 Nature and Extent of Contamination

This subsection describes the nature and extent of groundwater contamination at the NBPs. A small reach of an unnamed perennial tributary of Spring Creek flows inside the southwestern boundary of the NBP into the WBPA. However, because the largest portion of Spring Creek and perennial tributaries are present within the WBPA site boundary, surface water and sediment are evaluated under that IAAAP site (IAAP-032G). Surface water and sediment data near the NBPs is also discussed to support the fate and transport evaluation. Similarly, although soil has been addressed under OU-1, it is discussed briefly to inform the CSM for potential groundwater contaminants.

The source of contamination at the NBPs is attributed to releases to the surface as a result of historical site operations, including open burning of lead azide and gunpowder (JAYCOR, 1996). Incomplete combustion of explosives compounds and metals from ash released to soil may have leached into groundwater.

5.3.4.1 Groundwater

Groundwater samples have been collected at the NBPs since 1993. Five active monitoring wells are present at the NBPs. Four of the wells are screened in the overburden to depths ranging from 7 to 29 feet bgs; one well (JAW-14) is screened in shallow bedrock from 18 to 28 feet bgs (Figure 5.1-1). Historical groundwater samples were analyzed for analyzed for VOCs, SVOCs, explosives, metals, PAHs, and radionuclides. No PAHs were detected in historical groundwater samples, and SVOCs have not been detected in groundwater sampled since 1995 at the NBPs. Based on historical site operations and COCs identified in soil, explosives, VOCs, and metals are considered chemicals of interest in groundwater at the NBPs; however, metals and VOCs have been detected below screening criteria since 2000.

Samples were collected from all five NBP monitoring wells during the most recent RI activities, in 2019, and analyzed for explosives (Figure 5.1-4). Monitoring well JAW-13 was also analyzed for VOCs to address the data quality objectives for the WBPA (Section 5.2). Table 5.3-2 summarizes the chemicals detected in groundwater during the 2000–2019 sampling events at the NBPs. Summary tables of all the analytical results (including nondetects) from the 2018–2020 RI activities are provided in Appendix G. Summary tables of all historical analytical results from the NBPs are provided in Appendix H.

VOCs

Three VOCs (Freon 113, bromomethane, and chloroform) have been detected in groundwater at JAW-13 since 2000 (Table 5.3-2). The Freon 113 concentration detected at JAW-13 in 2019 was 2,000 µg/L, below the site characterization PAL (10,000 µg/L). This well is located near the southern boundary of the NBPs. No VOCs have been detected above their respective site characterization PALs at the NBPs.

Explosives

Between 2000 and 2020, five explosives (MNX, 3-nitrotoluene, 4-amino-2,6-DNT, HMX, and RDX) were detected at the NBPs (Table 5.3-2). No explosives were detected above their respective site characterization PALs at the NBPs during this time period. MNX does not have a site characterization PAL. Historically, only RDX has exceeded its site characterization PAL of 2 µg/L at one location (JAW-14), at a concentration of 2.1 µg/L (Appendix H). During the most recent sampling event in 2019, RDX was not detected at any of the five wells at the NBPs.

Metals

Eight metals have been detected in groundwater at the NBPs since 2000; however, no metals were detected above their site characterization PALs or BTVs. Concentrations of some metals may be naturally elevated in the environment, and may not indicate a CERCLA-regulated release. Several metals (such as barium, calcium, chromium, lead, magnesium, selenium, silver, and sodium) were detected below their BTVs during the latest sampling events and are therefore considered to be naturally occurring in groundwater at the NBPs.

5.3.4.2 Sediment and Surface Water

There is a small section of a perennial Spring Creek tributary that runs just inside the southern boundary of the NBPs. The tributary flows into the northern portion of the WBPA and into Spring Creek (Figure 5.1-1). Spring Creek and its perennial tributaries are located predominantly within the WBPA, and therefore these surface water features are discussed in more detail in Section 5.2. However, to support the CSM for the NBPs, the nature and extent of RDX in surface water and sediment samples that are near the NBPs are discussed in this subsection.

Figure 5.1-6 shows surface water and sediment samples that have been collected from the EDA for explosives analysis. Summary tables of historical analytical results are provided in Appendix H. RDX was detected in sample SCT1 in 2002; however, it was not detected in this location during subsequent sampling events, in 2003 and 2004 (Table 5.2-3). During the 2018–2020 RI sampling event, surface water samples were collected upstream (EDA-SW03) and downstream (EDA-SW02) of the EDA and analyzed for explosives (Table 5.2-3). RDX was not detected in any of the upstream or downstream surface water samples. As described above, no contaminants that would discharge into surface water were detected in groundwater at the NBPs above their site characterization PALs.

5.3.5 Fate and Transport

Neither explosives nor VOCs were detected in groundwater above their site characterization PALs during the most recent sampling event (2019). Metals were also not detected above their PAL or BTVs during the most recent sampling event (2003). Therefore, no chemicals of interest have been identified for fate and transport discussion at the NBPs based on a comparison of data to the site characterization PALs. Human health COPCs are identified in Section 5.3.6 in accordance with methods described in Section 4.

NBP-MW1 was installed downgradient of Pad 1-N, where low levels of RDX contamination above the OU-1 leachability RGs had been left in place. RDX was not detected in groundwater at this location; therefore, this location is not likely contributing to groundwater contamination.

5.3.6 Human Health Risk Assessment

An HHRA was prepared for the NBPs to evaluate potential current and future health risks and hazards from exposure to chemicals in site groundwater. Soil media within the NBPs is not included in the HHRA as it not a component of this RI; the soil RI was conducted under OU-1 (IAAP-036). A brief summary of OU-1 soil COCs is provided in Section 5.3.1.3 and historical remedial activities for soil are presented in Table 5.3-1. A very small reach of an unnamed perennial tributary of Spring Creek flows inside the southwestern boundary of the NBPs into the WBPA; however, surface water and sediment media are not included in this HHRA and are addressed with the WBPA HHRA (see Section 5.2.6).

The HHRA was conducted in accordance with the final UFP-QAPP (CH2M, 2017a), with the exception of some deviations that were agreed to during meetings or correspondence with USACE and USEPA following approval of the final UFP-QAPP. The approach and method used to conduct the HHRA are provided in Section 4.3.1. This section presents the CEM for the NBPs and provides the results of the four-step evaluation process comprising the following:

- Data evaluation.
- Exposure assessment.
- Toxicity assessment.
- Risk characterization.

The results of the HHRA are used to determine whether further action is warranted for groundwater at the NBP.

5.3.6.1 Conceptual Exposure Model

A description of the NBPs, their operational history, previous investigations, and remedial actions is provided in Sections 5.3.1 and 5.3.2. The soil at the NBPs is addressed under the remedy for OU-1 (IAAAP Site IAAP-036) (Leidos, 2018) and was not reevaluated in this HHRA.

The NBP is an inactive site that consisted of two earthen burn pads for open burning of lead azide and gunpowder. The EDA is fenced, and there are no remaining structures onsite. The site is closed to recreational activities; therefore, hunting is not permitted within the site boundary. There is a very small reach of an unnamed perennial surface water feature within the NBP site boundary; however, it flows into the WBPA, and therefore surface water and sediment are evaluated with the WBPA HHRA (see Section 5.2.6). There are culverts located at the NBPs; therefore, pathway for potential groundwater exposures by construction/utility workers is complete.

Groundwater is not currently being used as a potable water source and there are no plans to use groundwater for potable purposes in the future; however, based on applicable CERCLA policy and guidance, groundwater at the NBP is classified as Class IIB, a potential source of drinking water (USEPA, 1989). Therefore, the HHRA for the NBPs evaluates potential exposures to groundwater due to its potential future use as a drinking water source. This consists of the evaluation of future residential exposures to groundwater.

There are no potentially complete exposure pathways under current site conditions. The following potential future human receptors were identified in the HHRA for the NBPs:

- **Future Site Workers.** Future site workers could contact groundwater based on its potential future use as a drinking water source at the NBPs and could be exposed to indoor air (that may be impacted by VOCs migrating from groundwater) in buildings.

- **Future Construction/Utility Workers.** Future construction/utility workers could contact shallow groundwater while replacing a culvert located within the NBPs.

- **Future Hypothetical Residents.** Future hypothetical residents could contact groundwater based on potential future use as a drinking water source at the NBPs and could be exposed to indoor air (that may be impacted by VOCs migrating from groundwater) in buildings.

As discussed in Section 4.3.1, potential exposures and risks and hazards to future site workers and construction/utility workers are estimated in the HHRA only if the estimated risks and hazards for a hypothetical residential scenario exceed acceptable risk levels and COCs are identified for a residential scenario. The human health CEM presenting potential exposure media, exposure points, receptors, and exposure routes is provided in Appendix A-4 Attachment 1 (Table 1) and depicted graphically on Figure 5.3-1.

5.3.6.2 Data Evaluation

Data Used in the HHRA

The analytical data used in the HHRA consisted of groundwater samples collected at the NBPs. Groundwater samples collected from 2002 and 2003 and more recent samples, collected in 2019, were used in the HHRA for the NBPs. Historical groundwater samples were analyzed for explosives, metals, and one SVOC (1,4-oxathiane, which was nondetect at all locations). Recent groundwater samples were analyzed for explosives, one PAH (which was all nondetects), SVOCs (which were all nondetects), and VOCs. The analytical data for explosives and SVOCs from 2002 and 2003 were not included in the HHRA because data were available from the 2019 sampling event. As stated in the UFP-QAPP (CH2M, 2017), "Older data (i.e., data collected prior to 2012) may be used in the human health risk assessments if they are still representative of the site (i.e., groundwater flow is slow), chemicals have properties where there would not be a significant reduction in concentrations over time (e.g., metals), or data are conservative for site conditions." The NBPs are no longer operational, as described in Section 5.3.1. Potential soil sources to groundwater have been remediated, as described in Section 5.3.1.3. Due to a lack of continuing sources, historical concentrations in groundwater are expected to have remained stable or even decreased due to natural attenuation processes. Therefore, the assumptions in the final UFP-QAPP still hold. Samples collected prior to 2012 are considered representative of, or more conservative than, current conditions at the NBPs.

Eleven groundwater samples were used to evaluate potential exposures for both a potable use scenario and the VI pathway. The groundwater samples were not collected at multilevel wells; therefore, a separate data grouping (based on shallow groundwater only) was not used to evaluate the VI pathway. A separate groundwater data grouping was used to evaluate a construction/utility worker scenario, assuming construction/utility workers could be exposed to shallow groundwater (encountered at depths up to 10 feet bgs). Four groundwater samples were used to evaluate potential exposures in a trench for a construction/utility worker.

A summary of the number of chemicals analyzed and detected in groundwater is presented below:

Chemical Group	Number of Chemicals Analyzed	Number of Chemicals Detected
Groundwater		
Explosives	17	2
Metals	8	4
PAHs	1	0
SVOCs	5	0
VOCs	61	3

A description of the data groupings and samples included in the HHRA are provided in Tables 5.3-3 and 5.3-4, respectively. The analytical dataset used in the HHRA is included as Appendix A-4, Attachment 2. The groundwater sampling locations included in the HHRA are depicted on Figure 5.1-11.

Screening Results for Site-related Chemicals of Potential Concern and Naturally Occurring Chemicals

The approach and SLs used to select the COPCs (site-related COPCs or naturally occurring chemicals) are described in Section 4.3.1. The results of the COPC screening process for a future site worker and hypothetical resident potentially exposed to groundwater are provided in Appendix A-4, Attachment 1 (Tables 2.1 and 2.2), and those for a future construction/utility worker potentially exposed to groundwater in a trench are provided in Appendix A-4, Attachment 1 (Table 2.3). The tap water RSL for hexavalent chromium was used in the COPC screening process for total chromium because the groundwater samples collected at the NBPs were not analyzed for hexavalent chromium. The COPCs (site-related COPCs or naturally occurring chemicals) identified in site groundwater are summarized in the tables below.

Summary of COPCs for the NBP—Site-Related

Receptor	COPC	Frequency of Detections	Minimum Detection (µg/L)	Maximum Detection (µg/L)
Groundwater Used for Tap Water				
Future Site Worker and Future Hypothetical Resident	1,1,2-Trichlorotrifluoroethane (Freon 113)	1 / 1	2000	2000
Groundwater to Indoor Air via Vapor Intrusion				
Future Site Worker and Future Hypothetical Resident	1,1,2-Trichlorotrifluoroethane (Freon 113)	1 / 1	2000	2000

Summary of COPCs for the NBP—Naturally Occurring Chemicals

Receptor	COPC	Frequency of Detections	Minimum Detection (µg/L)	Maximum Detection (µg/L)
Groundwater Used for Tap Water				
Future Site Worker and Future Hypothetical Resident	Chromium	4 / 6	0.62	2.4
Shallow Groundwater in a Trench (<10 ft bgs)				
Future Construction / Utility Worker	Chromium	1 / 2	2.4	2.4

5.3.6.3 Exposure Assessment

NBP is an inactive site. There is a very small reach of an unnamed perennial tributary of Spring Creek within the NBP site boundary; however, potential exposures to surface water and sediment are addressed in the WBPA HHRA (Section 5.2.6). The site is closed to recreational activities; therefore, hunting is not permitted within the site boundary.

As previously discussed, groundwater is not being used as a potable water source; however, the HHRA for the NBPs evaluated potential exposures to groundwater due to its potential future use as a drinking water source. This consists of the evaluation of future residential exposures to groundwater. Therefore, ingestion and dermal contact exposures to COPCs in groundwater were estimated for future hypothetical residents. Additionally, inhalation exposures to site groundwater were also evaluated for hypothetical residents, assuming VOCs could be present in household air as a result of showering, bathing, and other household activities. The vapor intrusion pathway is also considered potentially complete for groundwater if future industrial buildings or residences are constructed at the NBP; therefore, potential inhalation exposures to indoor air were evaluated for hypothetical residents. Culverts are located at the NPBs; therefore, potential ingestion, dermal contact, and inhalation exposures to shallow groundwater in a trench were evaluated for future construction/utility workers.

As discussed in Section 4.3.1, the hypothetical resident is protective of all other activities; therefore, potential exposures and risks and hazards to future site workers and construction/utility workers are estimated in the HHRA only if the estimated risks and hazards for a hypothetical residential scenario exceed acceptable risk and hazard levels and COCs are identified for a residential scenario. The potential exposure pathways quantified in the HHRA are included in Appendix A-4, Attachment 1 (Table 1), and shown on Figure 5.3-1. The following receptor scenarios were quantified in the HHRA for the NBP:

- Future Site Worker
  - Groundwater (tap water) COPCs—ingestion and dermal contact
  - Groundwater (vapor intrusion) COPCs—inhalation of volatiles in indoor air
- Future Construction/Utility Worker
  - Shallow groundwater (trench, 0 to 10 feet bgs) COPCs—incidental ingestion and dermal contact
- Future hypothetical residents (adult and child)
  - Groundwater (tap water) COPCs—ingestion, dermal contact, and inhalation of volatiles in household air

– Groundwater (vapor intrusion) COPCs—inhalation of volatiles in indoor air

Risks and hazards for site workers and construction/utility workers were quantified in the HHRA because the estimated risks or hazards for a hypothetical residential scenario exceeded acceptable risk or hazard levels and COCs were identified for a residential scenario.

In accordance with *Determining Groundwater Exposure Point Concentrations, Supplemental Guidance* (USEPA, 2014b), groundwater EPCs are typically calculated based on the data collected in the core of a plume. However, based on available site data, no plumes are present. Therefore, all results in the groundwater dataset were used to calculate the EPCs for the COPCs in groundwater. For groundwater, fewer than eight samples were available in the data groupings used to evaluate a potable use scenario, the vapor intrusion pathway, and a trench scenario. Therefore, the maximum detected concentration was selected as the EPC for each COPC. The groundwater EPCs used to estimate the chemical intakes for each exposure scenario are provided in Appendix A-4, Attachment 1 (Tables 3.1 through 3.3).

The exposure factors used in the intake calculations for future receptor scenarios are included in Appendix A-4, Attachment 1 (Tables 4.1 through 4.3). The primary references for the exposure factor values are the standard default exposure factors presented in the HHEM (USEPA, 2014a).

5.3.6.4 Toxicity Assessment

The oral toxicity values (CSFs and RfDs) and inhalation toxicity values (IURs and RfCs) used in the HHRA were obtained from the USEPA standard hierarchy of toxicity value sources (USEPA, 2003), as provided in Section 4.3.1. Noncancer toxicity values for the COPCs identified at the NBPs are provided in Appendix A-4, Attachment 1 (Tables 5.1 and 5.2). Cancer toxicity values for the COPCs are provided in Appendix A-4, Attachment 1 (Tables 6.1 and 6.2).

One COPC (chromium, evaluated as hexavalent chromium in the HHRA) was identified as acting with a MMOA. The ADAFs and exposure assumptions used to calculate adjusted intakes and exposure concentrations for chromium are provided in Appendix A-4, Attachment 1 (Table 4 Supplement).

5.3.6.5 Risk Characterization

The risk characterization for NBP was completed using a four-step process, as discussed in Section 4.3.1. The results of each step are discussed below.

Step 1: Total Combined Risks and Hazards from Site-Related COPCs and Naturally Occurring Chemicals

Step 1 consists of calculating receptor-specific ELCRs and HIs that include contributions from both site-related COPCs and naturally occurring chemicals. The estimated risks and hazards for a hypothetical residential scenario are summarized below in Table 5.3-5.

Table 5.3-5. Summary of Total Combined Risk and Hazard Estimates for Site-Related COPCs and Naturally Occurring Chemicals—IAAP-036G: North Burn Pads Groundwater
Iowa Army Ammunition Plant, Middletown, Iowa

Receptor [a]	ELCR/HI Tables (RME) in Appendix A-4, Attachment 1	Exposure Medium	COPC/Chemical	NBP		
				EPC [b]	ELCR	HI
Hypothetical Resident (Adult)	7.1 and 9.1	Groundwater (Indoor Air)	1,1,2-Trichlorotrifluoroethane (Freon 113)	27400	NA	5
			Total HI (Groundwater—Indoor Air):		**NA**	**5**
		Groundwater	Chromium	2.4	NA	0.03

Table 5.3-5. Summary of Total Combined Risk and Hazard Estimates for Site-Related COPCs and Naturally Occurring Chemicals—IAAP-036G: North Burn Pads Groundwater

</table>

[a] ELCRs were estimated for the adult/child aggregate receptor based on lifetime exposure and noncarcinogenic HIs were estimated separately for adult and child residents.

[b] EPC Units: groundwater (indoor air)—µg/m³, groundwater (tap water)—µg/L

µg/L = microgram per liter
µg/m³ = microgram per cubic meter
COPC = chemical of potential concern
ELCR = excess lifetime cancer risk
EPC = exposure point concentration
HI = hazard index
NA = not applicable
RME = reasonable maximum exposure

Step 2: Risk Characterization of Naturally Occurring Chemicals

Step 2 consists of calculation of receptor-specific ELCRs and HIs for naturally occurring chemicals. One COPC (chromium) was identified as a naturally occurring chemical in site groundwater at the NBP, as discussed in Section 5.3.4. The maximum detected concentration of chromium in groundwater was less than its BTV. The estimated risks and hazards for the naturally occurring chemical in groundwater for a future hypothetical residential scenario are provided below in Table 5.3-6. The naturally occurring chemical is not used to identify the final COCs for the NBPs and is not discussed further in the HHRA after this step.

Table 5.3-6. Summary of Risk and Hazard Estimates for Naturally Occurring Chemicals—IAAP-036G: North Burn Pads Groundwater
Iowa Army Ammunition Plant, Middletown, Iowa

Receptor [a]	ELCR/HI Tables (RME) in Appendix A-4, Attachment 1	Exposure Medium	Chemical	NBP		
				EPC [b]	ELCR	HI
Hypothetical Resident (Adult)	7.4 and 9.4	Groundwater (Tap water)	Chromium	2.4	NA	0.03
	Total HI (Groundwater—Tap Water):				**NA**	**0.03**
Hypothetical Resident (Child)	7.5 and 9.5	Groundwater (Tap water)	Chromium	2.4	NA	0.05
	Total HI (Groundwater—Tap Water):				**NA**	**0.05**
Hypothetical Resident (Adult/Child Aggregate)	7.6 and 9.6	Groundwater (Tap water)	Chromium	2.4	6E-05	NA
	Total ELCR (Groundwater Tap Water):				**6E-05**	NA

Notes:

[a] ELCRs were estimated for the adult/child aggregate receptor based on lifetime exposure and noncarcinogenic HIs were estimated separately for adult and child residents.

[b] EPC Units: groundwater (tap water)—µg/L

µg/L = microgram per liter

COPC = chemical of potential concern

ELCR = excess lifetime cancer risk

EPC = exposure point concentration

HI = hazard index

NA = not applicable

RME = reasonable maximum exposure

Step 3: Risk Characterization of Site-related COPCs

Step 3 consists of calculating receptor-specific ELCRs and HIs associated with site-related COPCs. One site-related COPC (1,1,2-trichlorotrifluoroethane [Freon 113]) was identified for groundwater at NBP. The estimated risks and hazards for 1,1,2-trichlorotrifluoroethane) in groundwater for a future site worker and hypothetical resident are provided below in Table 5.3-7. An ELCR could not be estimated for 1,1,2-trichlorotrifluoroethane) because oral and dermal CSFs have not been established for it, based on the hierarchy of toxicity sources used in the HHRA (USEPA, 2003).

Table 5.3-7. Summary of Risk and Hazard Estimates for Site-Related COPC—IAAP-036G: North Burn Pads Groundwater

Iowa Army Ammunition Plant, Middletown, Iowa

Receptor [a]	ELCR/HI Tables (RME) in Appendix A-4, Attachment 1	Exposure Medium	COPC	NBP EPC [b]	NBP ELCR	NBP HI
Site Worker	7.7 and 9.7	Groundwater (Indoor Air)	1,1,2-Trichlorotrifluoroethane (Freon 113)	27400	NA	1
			Total ELCR and HI (Groundwater—Indoor Air):		**NA**	**1**
		Groundwater (Tap water)	1,1,2-Trichlorotrifluoroethane (Freon 113)	2000	NA	0.0006
			Total ELCR and HI (Groundwater—Tap Water):		**NA**	**0.0006**
	Total ELCR and HI (Groundwater—Indoor Air and Tap Water):				**NA**	**1**
Hypothetical Resident (Adult)	7.8 and 9.8	Groundwater (Indoor Air)	1,1,2-Trichlorotrifluoroethane (Freon 113)	27400	NA	5
			Total HI (Groundwater—Indoor Air):		**NA**	**5[c]**
		Groundwater (Tap water)	1,1,2-Trichlorotrifluoroethane (Freon 113)	2000	NA	0.2
	Total HI (Groundwater—Tap Water):				**NA**	**0.2**
	Total HI (Groundwater—Indoor Air and Tap Water):				**NA**	**5[c]**
Hypothetical Resident (Child)	7.9 and 9.9	Groundwater (Indoor Air)	1,1,2-Trichlorotrifluoroethane (Freon 113)	27400	NA	5
			Total HI (Groundwater—Indoor Air):		**NA**	**5[c]**
		Groundwater (Tap water)	1,1,2-Trichlorotrifluoroethane (Freon 113)	2000	NA	0.2
	Total HI (Groundwater—Tap Water):				**NA**	**0.2**
	Total HI (Groundwater—Indoor Air and Tap Water):				**NA**	**5[c]**
Hypothetical Resident (Adult/Child Aggregate)	7.10 and 9.10	Groundwater (Indoor Air)	1,1,2-Trichlorotrifluoroethane (Freon 113)	27400	NA	NA
			Total ELCR (Groundwater—Indoor Air):		**NA**	**NA**
		Groundwater (Tap water)	1,1,2-Trichlorotrifluoroethane (Freon 113)	2000	NA	NA
	Total ELCR (Groundwater—Tap Water):				**NA**	**NA**
	Total ELCR (Groundwater—Indoor Air and Tap Water):				**NA**	**NA**

Notes:

[a] ELCRs were estimated for the adult/child aggregate receptor based on lifetime exposure and noncarcinogenic HIs were estimated separately for adult and child residents.

[b] EPC Units: groundwater (indoor air)—µg/m^3, groundwater (tap water)—µg/L

[c] The HI for NOE (due to 1,1,2- Trichlorotrifluoroethane [Freon 113]) exceeds 1—Appendix A-4, Attachment 1 (see Table 9.8 and Table 9.9).

µg/L = microgram per liter

µg/m^3 = microgram per cubic meter

COPC = chemical of potential concern

ELCR = excess lifetime cancer risk

EPC = exposure point concentration

HI = hazard index

NA = not applicable

NOE = No Observable Effects

RME = reasonable maximum exposure

Step 4: Final COC Determination

For groundwater (vapor intrusion) exposures by future hypothetical residents, one target organ–specific HI ("no observed effects") exceeded USEPA's threshold of 1. The 1,1,2-trichlorotri-fluoroethane (Freon 113) groundwater (vapor intrusion) EPC for the future hypothetical resident was 27,400 µg/L. The HI for the hypothetical resident was 5; 1,1,2-trichlorotri-fluoroethane (Freon 113), which was identified as a COC in groundwater for future hypothetical residents (see Appendix A-4, Attachment 1 [Tables 10.1 and 10.2]). Therefore, potential exposures and risks and hazards were also estimated for future site workers (summarized in Table 5.3-7).

For exposures to groundwater (potable use and vapor intrusion) by future site workers, the cumulative HI, which was equal to 1 did not exceed the USEPA's acceptable HI of 1, and no COCs were identified for this receptor.

The final COCs are summarized in the table below.

Final Groundwater COCs

Future Hypothetical Resident		Future Site Worker	
Tap Water	**Indoor Air via Vapor Intrusion**	**Tap Water**	**Indoor Air via Vapor Intrusion**
None	1,1,2-Trichlorotrifluoroethane (Freon 113)	None	None

5.3.6.6 Uncertainty Analysis

The assumptions used in the HHRAs have inherent uncertainty. The general uncertainties associated with the HHRAs for the sites in this RI report are provided in Section 4.3.1. This section provides additional site-specific uncertainties associated with the HHRA for the NBPs that are not included in Section 4.3.1.

Total chromium was initially identified as a COPC in groundwater because the maximum detected concentration for total chromium exceeded the tap water RSL for hexavalent chromium. It is likely that some or all of the total chromium concentrations are in the trivalent chromium form. All of the groundwater chromium concentrations are less than the tap water RSL for trivalent chromium and the MCL and BTV for total chromium. Using the hexavalent chromium RSL to evaluate total chromium in the COPC selection process was a conservative approach in the HHRA. Total chromium was determined to be naturally occurring in groundwater at the NBPs.

Chemicals that were 100 percent not detected in an exposure medium were not included in the COPC identification process; however, they were evaluated in a separate screening to determine whether elevated nondetected results were present in site media. The analysis of the nondetected chemicals at the NBP is provided in Appendix A-4, Attachment 3. In summary, four explosives (2,4-dinitrotoluene, 2,6-dinitrotoluene, 2-nitrotoluene and nitrobenzene), one metal (arsenic), one PAH (naphthalene), two SVOCs (1,4-dichlorobenzene and hexachlorobutadiene), and 14 VOCs have RLs and/or DLs exceeding SLs at the NBP. Although the DLs and/or RLs for these nondetected chemicals are greater than the SLs, based on the acceptably low DLs and RLs, further consideration of nondetected chemicals does not appear warranted in the NBP HHRA.

5.3.6.7 Summary of HHRA

An HHRA was prepared for the NBPs to evaluate potential future health risks from exposure to chemicals in site groundwater. The NBPs is an inactive site. The site is closed to recreational activities, and therefore hunting is not permitted within the site boundary. There is a very small reach of an unnamed perennial tributary of Spring Creek within the NBP site boundary, and potential exposures to this surface water feature are evaluated in the WBPA HHRA (Section 5.2.6).

The following potential future human receptors were identified in the HHRA for the NBPs:

- **Future Site Workers.** Future site workers could contact groundwater based on potential future use as a drinking water source at the NBPs and could be exposed to indoor air (that may be impacted by VOCs migrating from groundwater) in buildings.

- **Future Construction/Utility Workers.** Future construction/utility workers could contact shallow groundwater while replacing a culvert located within the NBPs.

- **Future Hypothetical Residents.** Future hypothetical residents could contact groundwater based on its potential future use as a drinking water source at NBPs and could be exposed to indoor air (that may be impacted by VOCs migrating from groundwater) in buildings.

Potential exposures and risks and hazards to future site workers and construction/utility workers were estimated in the HHRA only if the estimated risks and hazards for a hypothetical residential scenario exceed acceptable risk and hazard levels and COCs were identified for a residential scenario.

The COPCs (site-related COPCs or naturally occurring chemicals) identified in site groundwater are as follows:

- Groundwater (potable):
  - Naturally occurring: chromium.
  - Site-related: 1,1,2-trichlorotrifluoroethane (Freon 113).
- Groundwater (vapor intrusion): 1,1,2-trichlorotrifluoroethane (Freon 113).

The risk characterization for the NBPs was completed using a four-step process as discussed in Section 4.3.1. Step 1 presents the total combined risks and hazards[6] from site-related COPCs and naturally occurring chemicals, as summarized in Table 5.3-5. Step 2 presents the risks and hazards from naturally occurring chemicals, as summarized in Table 5.3-6. Step 3 presents the risks and hazards from site-related chemicals, as summarized in Table 5.3-7.

[6] In Steps 1 and 2 of the risk characterization, chromium (total) concentrations were assumed to be hexavalent chromium due to the lack of speciated data.

Unacceptable groundwater hazards were identified in Step 3 for hypothetical residents based on the potential vapor intrusion pathway, and in Step 4, 1,1,2-trichlorotrifluoroethane (Freon 113) was identified as a potential vapor intrusion COC for future hypothetical residents. However, the current and expected future Land Use of the NBPs is Commercial/Industrial so future VI exposures to residents is not likely or realistic. Because a COC was identified for hypothetical residents, groundwater risks and hazards were also estimated for future site workers. No COCs were identified for future site workers.

In summary, the following COCs were identified for groundwater:

Future Site Worker	Future Hypothetical Resident
None	1,1,2-Trichlorotrifluoroethane (Freon 113)

5.3.7 Ecological Risk Assessment

The ERA for groundwater at the NBPs is presented herein, beginning with Step 1 of the ERA process (to determine whether there are complete exposure pathways). Soil at the NBPs is already addressed under the remedy for OU-1. While a perennial tributary of Spring Creek runs just inside the southern boundary of the site; surface water and sediment from this feature were evaluated during the watershed ERA (Appendix I). A summary of the ERA conclusions for Spring Creek and its perennial tributaries is provided in the ERA for the WBPA (Section 5.2.7).

Groundwater is present onsite, but ecological receptors are not exposed directly to groundwater; nevertheless, groundwater is a transport medium, and contaminated groundwater has the potential to migrate to and discharge to surface water bodies. Other than the small portion of the Spring Creek tributary than runs through the NBPs (and is evaluated under the WBPA site), there is a lack of perennial surface water bodies on the NBPs. Therefore, the groundwater-to-surface-water exposure pathway is incomplete. There are no complete exposure pathways for ecological receptors on the site. Therefore, there are no adverse effects identified and no additional actions are required from an ecological perspective.

5.3.8 Conclusions and Recommendations

An RI was conducted for the NBPs to refine the nature and extent of contamination in groundwater from historical activities and assess for potentially unacceptable risk to human health and adverse effects to the environment. Analytical data available for groundwater at NBPs includes data for explosives, VOCs, SVOCs, PAHs, radionuclides, and metals. Of these, explosives, VOCs, and metals were identified as site-related chemicals of interest based on historical site operations and a comparison of concentration data to site characterization PALs and BTVs (See Section 4.1).

In groundwater, no VOCs, explosives, or metals were detected above their site characterization PAL or BTV (if available) during the most recent sampling events. Freon 113 was detected in groundwater in one well; however, concentrations were below the site characterization PAL, which differs from the screening value used for HHRA. This well (JAW-13) is located near the southern boundary of the NBPs and may represent the northern edge of VOCs observed in groundwater at the WBPA (Section 5.2). During the most recent sampling event in 2019, RDX was not detected at any wells at the NBPs. Given the lack of RDX in groundwater during the current RI, the soil removal that was completed in 1998 is assumed to have removed RDX contamination that could be a source to groundwater.

An HHRA and an ERA were conducted to quantify potential risks to human health and the environment from exposure to contaminants at the NBPs. The following conclusions were made based on the risk assessments:

- The HHRA identified potentially unacceptable risks for the following media and receptors:

  - **Future Hypothetical Residents.** For groundwater, potentially unacceptable risks and hazards were identified from exposure to 1,1,2-trichlorotrifluoroethane (Freon 113) through a potential vapor intrusion pathway. Therefore, this analyte was identified as a potential vapor intrusion COC for future hypothetical residents. However, the current and expected future Land Use of the IAAAP is Commercial/Industrial so future exposures to residents is not likely.
  - **Future Site Workers.** No potentially unacceptable risks or hazards were identified for exposure to groundwater.
- The ERA concluded that there are no adverse effects to ecological receptors identified and no additional actions are required from an ecological perspective.

Based on the results of the RI and risk assessments, additional action is warranted to mitigate potentially unacceptable risks to future receptors from the site-related COC (Freon 113) in groundwater at the NBPs. It is recommended that an FS be conducted under OU-10 to evaluate remedial alternatives to address the unacceptable risks in groundwater at the NBPs (IAAP-036G). When remedial alternatives are developed, the FS should consider ongoing site operations and the reasonably foreseeable future land use for this area.

5.4 North Burn Pads Landfill—Groundwater (IAAP-037G)

This subsection summarizes RI activities at the NBPLF site within the EDA. This report documents the RI for groundwater at the NBPLF (IAAP-037G). Soil is addressed under the remedy for OU-1 (IAAP-037) (Leidos, 2018). There are no perennial surface water features within the NBPLF, however Spring Creek flows adjacent to several environmental sites within the EDA (Figure 5.1-1). Because the largest portion of Spring Creek and perennial tributaries are within the WBPA site boundary, risk assessment of surface water and sediment is evaluated under that IAAAP site (IAAP-032G) (Section 5.2).

5.4.1 Background

5.4.1.1 Site Description

The NBPLF is an approximately 3-acre site located in the northeast portion of the IAAAP facility, within the Spring Creek watershed (Figure 5.1-1). The NBPLF is part of a larger area, the EDA. It is located just north of the CWP site (IAAP-024), which is addressed in the OU-12 RI report.

The NBPLF consists of a former landfill measuring 60 by 470 feet that was capped with clay, after the contents of the landfill were removed, as part of a cleanup operation in 1980 (JAYCOR, 1992; ECC, 2000). One building, BG-199-4, is present at the NBPLF and is currently used as a breakroom for AO staff. Additional activities at this site include disposal in dumpsters of slightly contaminated explosives waste approved by USEPA (USEPA, 1983, 2001b) and RCRA 90-day hazardous waste storage of paint filters (contaminated with aluminum epoxy paint), which are shipped offsite for disposal at approved facilities (USEPA, 2018a).

5.4.1.2 Operational History

The NBPLF was active between 1968 and 1972. Operations at the NBPLF consisted of the disposal of ash residue from NPBs' burning operations (see Section 5.3), as well as flashed cans, containers, and construction debris. Historical documents indicate that the Atomic Energy Commission used the EDA until 1975 (USACE, 2001); however, the NBPs were not impacted by radiological contamination (USACE, 2008).

5.4.1.3 Previous Investigations and Remedial Actions

Numerous investigations have been conducted at IAAAP since the 1980s. Table 5.4-1 summarizes the previous investigations and remedial actions conducted at the NBPLF, including conclusions and recommendations. Although soil at the NBPLF has already been addressed under OU-1, previous investigations for soil are also presented in Table 5.4-1 to support the CSM.

This report summarizes the RI for groundwater at the NBPLF (IAAP-037G). Previous investigations pertinent to the RI for groundwater are listed below; additional details on these investigations (including a more detailed description of work completed, as well as work not pertinent to this RI), are included in Table 5.4-1. Previous groundwater sampling locations are shown on Figure 5.1-2.

Investigation	Conclusion
Follow-on Study of Environmental Contamination (Battelle, 1984)	Two surface water samples were collected from Spring Creek, upstream and downstream of the EDA, and analyzed for explosives. No contamination was found in surface water at the EDA. No additional recommendations were made for the EDA sites.

Investigation	Conclusion
RCRA Facility Assessment (Ecology and Environment, 1987)	Three sediment samples were collected from the EDA and analyzed for explosives and metals. Significant levels of explosives (RDX, HMX, 1,3,5-TNB, and TNT) were detected. High metals concentrations were found upgradient and downgradient of the site. Heavy metals concentrations upgradient and downgradient of the open burning pit were high. Additional sediment sampling was recommended.
Facility-wide Preliminary Assessment (JAYCOR, 1994)	The Preliminary Assessment indicated there was a potential for contamination at the NBPLF; however, no specific contamination study had been performed in this area. It was concluded that the potential for overland contaminant migration may exist via the intermittent ravine north of the landfill. Removal actions that have taken place led to the conclusion that contaminant migration or exposure is low at the NBPLF.
Facility-wide Site Inspection (JAYCOR, 1992)	No groundwater samples were collected at the NBPLF during the SI. Three sediment samples were collected within the tributary north of the NBPLF. Several metals were detected in all the sediment samples. Chromium and selenium were detected slightly above their screening levels but were within background levels. No explosives were reported in any of the SI samples above their screening levels. No further investigation was recommended as part of the RI.
Phase I and Follow-on Remedial Investigation (JAYCOR, 1993, 1996)	Although the SI recommended no further investigation of the NBPLF, groundwater investigation was completed per USEPA request. Three new monitoring wells (JAW-625 through JAW-627) were installed and sampled for metals, explosives, SVOCs, and VOCs during follow-on work. In groundwater, explosives and metals were detected in all three monitoring wells. The highest levels of explosives were detected in JAW-626 (HMX at 11.2 µg/L). Chromium was reported at the highest levels, 13.2 µg/L, at JAW-627. VOCs were detected in only one upgradient monitoring well (JAW-625). No compliance monitoring was recommended at the NBPLF.
Periodic Groundwater and Surface Water Monitoring (multiple reports)	Periodic groundwater and surface water sampling was conducted at the NBPLF between the 1996 and 2008 as part of the FFA compliance monitoring and groundwater monitoring program. Samples were analyzed for metals, explosives, and/or gross alpha and gross beta parameters. During the last periodic sampling event, in 2008, only one groundwater sample was collected from JAW-627 and analyzed for RDX. In groundwater between 2000 and 2008, metals were detected below screening levels. RDX was the only explosive at the NBPLF to exceed its screening level (2 µg/L) at JAW-627.
Supplemental Groundwater Remedial Investigation (MWH, 2001)	Groundwater samples were collected from three existing monitoring wells (JAW-625 through JAW-627) and analyzed for VOCs, SVOCs, explosives, and metals. RDX was detected in two monitoring wells (JAW-625 and JAW-627) above its screening level.
Baseline Ecological Risk Assessment Sampling (MWH, 2004)	Sediment and surface water samples were collected as part of the BERA and analyzed for metals, explosives, SVOCs, pesticides, PCBs, and herbicides. One surface water and one sediment sample (SC13-H) were collected upstream of the NBPLF, one surface water and one sediment sample (SC08-H) downstream of the NBPLF, and three surface water and three sediment samples downstream of the EDA (SC09-H, SC10-H, SC11-H). Surface water samples SC13-H and SC08-H had RDX concentrations above screening levels in 2000. No explosives were detected in sediment samples.
Comprehensive Watersheds Evaluation and Supplemental Data Collection Work Plan (Tetra Tech, 2006)	The work plan concluded that no groundwater, surface water, or sediment data gaps were present at the NBPLF.

During the 1980 landfill closure, all contents of the landfill were removed to the Inert Disposal Area (JAYCOR, 1992). No known sampling was conducted at that time.

As part of the previous investigations under OU-1, explosives, VOCs, SVOCs, pesticides, and metals were identified as soil COCs for the EDA (ECC, 2000). Elevated levels of metals and explosives were identified in soil around former landfill (ECC, 2000); the former landfill area is shown on Figure 5.1-1. To address risks and hazards associated with these COCs, soil removal actions have been conducted at NBPLF, and LUCs have been implemented (Leidos, 2019); excavation areas are shown on Figure 5.1-1. Approximately 13,890 cubic yards of contaminated soil was removed from excavations around the former landfill. Confirmation samples verified that all soil COCs were removed to OU-1 remedial goals, with the exception of RDX. RDX exceeded its leachability remedial goal in one confirmation sample from the NBPLF at 2.5 mg/kg. The USEPA and USACE approved the backfilling of the excavation area given that contaminant concentrations were low, the remaining contamination was deep in the soil profile and would be covered with clean soil, human health and ecological risk would be minimal at the site, and removal of additional soil considering the contaminant depth and low risk potential was not cost-effective (USACE, 2016).

5.4.2 2018–2020 Remedial Investigation Activities

Additional field work was conducted at the NBPLF to resolve data gaps needed to complete the RI for groundwater (IAAP-037G). As documented in the final *Site-specific Worksheets for Operable Unit 6 of the Uniform Federal Policy–Quality Assurance Project Plan for Remedial Investigation at Iowa Army Ammunition Plant (Packet 2*) (CH2M, 2018a), the explosives plume required further horizontal and vertical delineation, particularly around JAW-627. In addition, an improved understanding of current conditions was warranted to complete the RI. To address these data gaps, the installation of two overburden monitoring wells and three bedrock monitoring wells was proposed along with groundwater sampling of three existing wells and the newly installed monitoring wells. Fieldwork completed at the NBPLF was conducted in accordance with the UFP-QAPP (CH2M 2018a).

As discussed in the final UFP-QAPP (CH2M, 2018a), surface water monitoring of Spring Creek was also warranted to assess potential groundwater and surface water interactions. This field work was conducted under the WBPA investigation and is included in Section 5.2.

5.4.2.1 2018–2019 Field Activities

Between June 5 and July 18, 2018, one new bedrock monitoring well (NBPLF-MW3) and one new overburden monitoring well (NBPLF-MW5) were installed at the NBPLF to meet the data quality objectives (Figure 5.1-2). Installation of two additional overburden locations (NBPLF-MW2 and NBPLF-MW7) were attempted; however, the locations were dry and no wells were installed. Two additional bedrock wells (NBPLF-MW4 and NBPLF-MW6) were installed in April 2020, as discussed in Section 5.4.2.2.

Station ID	Groundwater Unit	Total Depth (Feet bgs)	Screen Interval (Feet bgs)	Rationale
NBPLF-MW2a	Overburden	27	Dry, no well installed.	To horizontally delineate overburden groundwater conditions east of the former landfill.
NBPLF-MW3	Bedrock	68	57–67	To vertically delineate RDX in bedrock groundwater associated with JAW-627 and east of the former landfill, as detailed in Section 5.4.2.2.

Station ID	Groundwater Unit	Total Depth (Feet bgs)	Screen Interval (Feet bgs)	Rationale
NBPLF-MW4	Bedrock	35	24.5–34.5	To horizontally delineate RDX in bedrock groundwater associated with JAW-627, as detailed in Section 5.4.2.2.
NBPLF-MW5	Overburden	49	39–49	To delineate groundwater contamination adjacent to (north of) the former landfill and Building BG-199-4, as detailed in Section 5.4.2.2.
NBPLF-MW6	Bedrock	38	26.5–36.5	To horizontally delineate bedrock groundwater north of JAW-627.
NBPLF-MW7	Overburden	31	Dry, no well installed.	New location attempted to vertically delineate RDX in overburden groundwater associated with JAW-627, as detailed in Section 5.4.2.2.

New monitoring wells were drilled via rotosonic drilling techniques with a MiniSonic drill rig and 6-inch drill rods (overburden) and wireline (bedrock) or with a Geoprobe 6620DT drill rig with 6- and 8-inch-outer-diameter augers (shallow overburden) in accordance with the methods outlined in Section 3.2.3. Boring logs are provided in Appendix C. All proposed overburden monitoring well locations were drilled to bedrock. Bedrock monitoring well locations were drilled to depths between 35 and 68 feet bgs, consistent with the UFP-QAPP (CH2M, 2018a).

As summarized in the table above, groundwater was not present in the overburden to the northeast (proposed NBPLF-MW2, NBPLF-MW7), and only one new monitoring well (NBPLF-MW5) could be installed within this aquifer unit. In accordance with the UFP-QAPP, the overburden monitoring well (NBPLF-MW5) was screened across the perceived water table, just above bedrock. Well construction details are provided in Table 5.1-2. NBPLF-MW5 was completed with a 2-inch-nominal-diameter Schedule 40 PVC screen and riser and 0.5-foot Schedule 40 PVC end cap. The monitoring well was screened with a machine-slotted, 0.010-inch, 10-foot screen. The monitoring well was constructed with a certified-clean silica sand filter pack from the base of the borehole to 2 feet above the top of the screen. A 3-foot-thick bentonite layer was placed above the filter pack sand and hydrated. The well was grouted to the surface, and a steel stickup well protector was installed and surrounded by three bollards. Well completion diagrams are included in Appendix C.

Only one bedrock monitoring well, NBPLF-MW3, was installed in 2018. This bedrock monitoring well boring was cored to 68 feet bgs to look for groundwater presence in the bedrock cores. Based on field observations (such as fracture frequency and moisture content), the bedrock well was screened across intervals that were the mostly likely to produce groundwater. Once the screen interval was selected, the borings were reamed with 6-inch drill rods via sonic drilling techniques to the identified monitoring well depth. Well construction details are provided in Table 5.1-2. Bedrock monitoring well NBPLF-MW3 was completed with a 2-inch-nominal-diameter Schedule 40 PVC screen and riser and 0.5-foot Schedule 40 PVC end cap. NBPLF-MW3 was screened with a machine-slotted, 0.010-inch, 10-foot screen. Centralizers were installed at the base of and just above the screened interval, at 67 and 57 feet bgs. The monitoring well was constructed with a certified-clean silica sand filter pack from the base of the reamed borehole to 2 feet above the top of the screen. A 4-foot-thick bentonite layer was placed above the filter pack sand and hydrated. The well was grouted to the surface, and a steel stickup well protector was installed and surrounded by three bollards. Well completion diagrams are included in Appendix C.

Between June 19 and August 20, 2018, newly installed monitoring wells NBPLF-MW3 and NBPLF-MW5 were developed as described in Section 3.2.4. Both NBPLF-MW3 and NBPLF-MW5 were purged dry at least once, and over three well casing volumes were purged during development. Both NBPLF-MW3 and NBPLF-MW5 were considered developed due to the slow recharge. The well development logs are provided in Appendix C.

Groundwater samples were collected from three existing NBPLF monitoring wells (JAW-626, JAW-627, and NBPLF-MW1), one existing CWP monitoring well (CW-P), and one newly installed monitoring well (NBPLF-MW5) on June 24 and 25, 2018. Newly installed monitoring well NBPLF-MW3 was sampled on March 25, 2019. NBPLF monitoring wells were sampled via low-flow purging and sampling techniques or by purging three well casing volumes and analyzed for explosives by Method SW8330B. Purge logs are included in Appendix C. Data were managed and validated as discussed in Section 3.3. Laboratory reports are provided in Appendix B.

All IDW generated during activities (soil and purge water) was disposed of in accordance with management activities discussed in Section 3.2.9. Waste management documentation is provided in Appendix D.

Newly installed monitoring wells NBPLF-MW3 and NBPLF-MW5 were surveyed by Bruner, Cooper, and Zuck, Inc., licensed Iowa surveyors, on September 24, 2018, in accordance with methods in Section 3.2.7. Existing monitoring well JAW-627 was resurveyed on December 17, 2019, to confirm the well location. Survey information is included in Appendix E.

5.4.2.2 Deviations and Follow-on Field Activities (2020)

The final UFP-QAPP (Packet 2) (CH2M, 2018a) proposed the installation of five new monitoring wells (two overburden and three bedrock wells) to delineate the explosives plumes at the NBPLF, particularly around the former landfill and around JAW-627. However, during the 2018 field activities, it was noted that JAW-627 was incorrectly located on the site figures. Therefore, only three out of the five proposed monitoring wells were attempted until the location of JAW-627 could be confirmed. JAW-627 was resurveyed on December 17, 2019, and was confirmed to be located east-southeast of the where it was previously assumed to be. Of note is that NBPLF-MW5 was installed where JAW-627 was originally believed to be (just north of the former landfill and Building BG-199-4) to provide groundwater data from beneath the former landfill. A new overburden location, NBPLF-MW7, was drilled adjacent to JAW-627 to meet the initial objectives of vertically delineating RDX in overburden groundwater associated with JAW-627. However, this location was dry, and no monitoring well was installed. This did not impact the results of the RI since the lack of groundwater in the overburden provides the necessary conceptual site model information.

To meet the final data quality objectives, proposed wells NBPLF-MW4 and NBPLF-MW6 were relocated south and north of JAW-627, respectively, to provide horizontal delineation. JAW-627, screened 27.5 to 37.5 feet bgs, is designated a shallow bedrock monitoring well. NBPLF-MW3, screened 57 to 67 feet bgs, was installed in 2018 adjacent to JAW-627 and provides vertical delineation. New bedrock monitoring wells (NBPLF-MW4 and NBPLF-MW6) were drilled via rotosonic techniques with a MiniSonic drill rig and 6-inch drill rods in accordance with methods outlined in Section 3.2.3. The borings were drilled to between 35 and 38 feet bgs, which is a depth similar to that of JAW-627. The boring logs are provided in Appendix C. The relocation of wells NBPLF-MW4 and NBPLF-MW6 did not impact the results of the RI since the new locations were selected to provide the necessary conceptual site model information.

Bedrock monitoring well borings for NBPLF-MW4 and NBPLF-MW6 were cored to look for groundwater presence in the bedrock cores. Based on field observations (such as, fracture frequency and moisture content), the bedrock well was screened across intervals that were the mostly likely to produce groundwater and to match JAW-627. Well construction details are provided in Table 5.1-2. Bedrock monitoring wells were completed with a 2-inch-nominal-diameter Schedule 40 PVC screen and riser and 0.5-foot Schedule 40 PVC end cap. Wells were screened with a machine-slotted, 0.010-inch, 10-foot screen. The monitoring wells were constructed with a certified-clean silica sand filter pack from the base of the reamed borehole to 1.5–2 feet above the top of the screen. A 3- to 3.5-foot-thick bentonite layer was placed above the filter pack sand and hydrated. The well was grouted to the surface, and a steel stickup well protector was installed and surrounded by three bollards. Well completion diagrams are included in Appendix C.

On April 18, 2020, newly installed monitoring wells NBPLF-MW4 and NBPLF-MW6 were developed in accordance with methods outlined in Section 3.2.4. NBPLF-MW6 was purged dry after approximately 2.5 well casing volumes were extracted, and the well was considered developed due to the slow recharge. NBPLF-MW4 was developed once parameters were stabilized and approximately 7.5 well casing volumes were extracted. Well development logs are provided in Appendix C.

Groundwater samples were collected from newly installed monitoring well, NBPLF-MW4 via low-flow purging and sampling techniques on April 20, 2020. NBPLF-MW6 was purged dry, and a groundwater sample was collected once the well had recharged on April 21, 2020. The groundwater samples were analyzed for explosives by Method SW8330B. Data were managed and validated as discussed in Section 3.3. Laboratory reports are provided in Appendix B.

All IDW generated during activities (soil and purge water) was disposed of in accordance with management activities discussed in Section 3.2.9. Waste management documentation is provided in Appendix D. Newly installed monitoring wells NBPLF-MW4 and NBPLF-MW6 were surveyed by Bruner, Cooper, and Zuck, Inc., licensed Iowa surveyors, on June 2, 2020, in accordance with methods outlined in Section 3.2.7. Survey information is included in Appendix E.

5.4.3 Environmental Setting

5.4.3.1 Topography and Surface Water

The topography at the NBPLF slopes to the east and north towards Spring Creek. Surface drainage near the NBPLF is through intermittent tributaries that channel surface water flow eastward into Spring Creek. The western portion of the site contains an asphalt parking lot on the south side of Building BG-199-4, while the eastern portion of the side is vegetated.

5.4.3.2 Geology and Hydrogeology

The overburden geology of the NBPLF consists of glacial till overburden. The till is primarily sandy clay containing discontinuous localized sand lenses. The overburden overlies the bedrock of the Warsaw Formation. The bedrock is composed of shale and limestone encountered at depths ranging from 19 to below 49 feet bgs near the NBPLF. Bedrock appears to be undulating at the NBPLF and is observed shallower in the eastern portion of the site than in the west and central portions of the site.

Groundwater in the overburden and shallow bedrock is generally encountered between 1 and 10 feet bgs, with the shallowest measurements recorded in the eastern portions of the NBPLF. Groundwater appears to be present under both unconfined (in the eastern portion of the NBPLF) and confined (in the western portion of the NBPLF) conditions. During the 2019 EDA-wide gauging event, shallow groundwater was measured between 11 and 21 feet bgs (Table 5.1-3). Deep groundwater occurs at depths ranging from approximately 11 to 34 feet bgs and was measured at approximately 33 feet at NBPLF-MW3 in 2019. NBPLF-MW4 and NBPLF-MW6 were not gauged during the sitewide event, as these locations were not yet installed. However, during sampling, depth to water was measured at 33 feet btoc (Table 5.1-5). Proposed monitoring well, NBPLF-MW2, was drilled to refusal at approximately 31 feet bgs and was dry, indicating groundwater is predominantly within the shallow bedrock in the northeast portion of this site.

The groundwater potentiometric surface in monitoring wells at the NBPLF vary due to the different aquifer zones that individual wells are screened in and the variable thicknesses of the overburden and transition zone to bedrock across this area. As a result, groundwater elevation contours were not drawn across the NBPLF (Figure 5.1-3). However, the groundwater flow direction at the NBPLF can be estimated by reviewing the groundwater elevations across the larger EDA area and considering the influence of Spring Creek on shallow groundwater flow. Based on recent and historical groundwater gauging across the EDA, overburden groundwater at the NBPLF is assumed to flow towards Spring Creek, primarily in east and southeast directions (Figure 2-2 and Figure 5.1-3). Hydraulic horizontal gradients were not measured in 2019 at the NBPLF; however, historical gradients have measured between 0.038 and 0.091 ft/ft at the NBPLF. Hydraulic conductivity values were calculated from slug tests and ranged from 0.0015 to 8.6 ft/day in the overburden (Tetra Tech, 2012). Based on 2019 groundwater elevations, a downward vertical gradient of -0.05 ft/ft was observed at the well pair JAW-627 (shallow bedrock) and NBPLF-MW3 (deep bedrock); groundwater elevations are provided on Table 5.1-3.

Historical gauging data indicate periodic discharge of groundwater to surface water is possible, as indicated by the elevation of periodic surface water in the intermittent tributary to the east of JAW-626 (Tetra Tech, 2012). During the 2019 gauging event, this tributary was dry.

5.4.4 Nature and Extent of Contamination

This subsection describes the nature and extent of groundwater contamination at the NBPLF. There are no perennial surface water features at the NBPLF. Similarly, although soil has been addressed under OU-1, it is discussed briefly to inform the CSM for potential groundwater contaminants. The source of contamination at the NBPLF is attributed to releases to the surface and subsurface as a result of historical site operations, including historical burial of waste within the NBPLF (JAYCOR, 1996).

Groundwater samples have been collected at the NBPLF since 1995. Seven active monitoring wells are present at the NBPLF. In addition, one monitoring well (CW-P) located at the CWP (IAAP-024) has also been monitored during NBPLF investigations due to its proximity to the site. Five of the wells are screened in the overburden to depths ranging from 7.5 to 49 feet bgs, and three wells are screened in bedrock from 24.5 to 68 feet bgs (Figure 5.1-1). Historical groundwater samples were analyzed for analyzed for VOCs, SVOCs, explosives, metals, PAHs, pesticides, and radionuclides. No PAHs, PCBs, pesticides, or SVOCs were detected in historical groundwater samples. Based on historical site operations and COCs identified in soil, explosives, VOCs, and metals are considered chemicals of interest in groundwater at the NBPLF; however, metals and VOCs have been detected below screening criteria since 1995. No VOCs have been detected at the NBPLF since 2000. Additionally, gross alpha and gross beta were detected below their MCLs (15 pCi/L and 50 pCi/L, respectively) in 1999 and 2000 at the NBPLF.

Samples were collected from all seven NBPLF monitoring wells and one CWP monitoring well (CW-P) during the most recent RI activities, in 2018 through 2020, and analyzed for explosives (Figure 5.1-4). Table 5.4-2 summarizes the chemicals detected in groundwater between 2000 and 2020 sampling events at the NBPLF. Summary tables of all the analytical results (including nondetects) from the 2018–2020 RI activities are provided in Appendix G. Summary tables of all historical analytical results from the NBPLF are provided in Appendix H.

Explosives

Between 2000 and 2020, seven explosives (MNX, 1,3-dinitrobenzene, 4-amino-2,6-DNT, TNX, DNX, HMX, and RDX) were detected at the NBPLF (Table 5.4-2). All explosives were detected below their respective site characterization PALs, except for RDX. During the latest sampling events, in 2018 through 2020, RDX exceeded its site characterization PAL at three locations (JAW-627, NBPLF-MW4, and NBPLF-MW6).

RDX contamination is present as two small plumes at the NBPLF. The largest plume is located along the eastern boundary of the site. During the current RI, in 2018, the maximum RDX concentrations were detected at deep overburden well JAW-627, at 14 µg/L (Figure 5.1-4). RDX concentrations in groundwater at the NBPLF decrease with depth and RDX was not detected in the adjacent bedrock well, NBPLF-MW3. Of note, RDX was also not detected in surface water samples collected in 2018 as part of this RI, which are due northeast and southeast of the NBPLF (Figure 5.1-6), which indicates that this eastern plume is defined and not impacting surface water. The second RDX plume is isolated and defined by the RDX that was historically detected at overburden well JAW-625. Low-level concentrations above the PAL (ranging between 4.7 µg/L and 9.5 µg/L) were detected at that location. JAW-625 was abandoned in 1998 during the soil removal action at the NBPLF. RDX was not detected in nearby NBPLF-MW1 during the current RI (2018–2020). Therefore, RDX concentrations in this second plume may have attenuated below the site characterization PAL.

Metals

Nine metals have been detected in groundwater at the NBPLF since 2000; however, no metals were detected above their site characterization PALs or BTVs. Concentrations of some metals may be naturally elevated in the environment, and may not indicate a CERCLA-regulated release. Several metals (such as cadmium and chromium) were detected below their BTVs during the latest sampling events and are therefore considered to be naturally occurring in groundwater at the NBPLF. During the most recent sampling event in 2004, antimony was reported in one well (JAW-626) at a low concentration of 4.1 B µg/L (Appendix H), just above the BTV (2.2 µg/L). However, the B qualifier indicates that antimony was also detected in the associated method and/or calibration blank, and this monitoring well concentration is likely biased high. Antimony was detected below its BTV during previous sampling events; therefore, antimony is considered to be naturally occurring at the NBPLF.

5.4.5 Fate and Transport

This section discusses the fate and transport of site-related chemicals of interest at the NBPLF. This includes chemicals that were detected above both their site characterization PAL and BTV (if available), during the last sampling event that those chemicals were analyzed. In groundwater, the only potential site-related chemical of interest is RDX. Fate and transport characteristics for this chemical were described in Section 3.2.

The NBPLF was formerly used for disposal of ash residue from NPBs' burning operations, as well as flashed cans, containers, and construction debris. The site is no longer an active landfill and is currently used for temporary waste storage, including of slightly contaminated explosives waste, which is placed in dumpsters and shipped offsite for disposal at approved facilities. Building BG-199-4 is located in place of the former landfill and surrounded by an asphalt parking lot. The eastern portion of the site is vegetated and sloped to the east, toward Spring Creek. Surface water drainage occurs through a number of intermittent drainage ditches that ultimately discharge to Spring Creek.

The source of contamination at the NBPLF is attributed to unintended releases to the surface and subsurface as a result of historical site operations, including landfill operations. Contaminants in groundwater have been transported from the source release areas through advection and dispersion. Groundwater generally flows southeast towards Spring Creek (Figure 5.1-3). Historical hydraulic gradients have been measured from 0.038 to 0.091 ft/ft at the NBPLF. Hydraulic conductivity values were calculated from slug tests and range from 0.0015 to 8.6 ft/day in the overburden (Tetra Tech, 2012). Vertical migration at the site is also limited by the generally tight clay lithology in the overburden and a decrease of fractures in bedrock with depth.

One RDX plume is present at the NBPLF east of the former landfill and is restricted to within the shallow bedrock. A second RDX plume, had been located around abandoned monitoring well JAW-625; however, RDX concentrations may have attenuated since the 1998 soil removal action. JAW-625 was abandoned during the removal action, but RDX has not been detected in monitoring well NBPLF-MW1, which was installed to replace this monitoring point (Figure 5.4-1).

Natural attenuation mechanisms that are potentially active at the NBPLF were evaluated. Natural attenuation includes various physical, chemical, or biological processes that under favorable conditions act without human intervention to reduce the mass, toxicity, mobility, volume, or concentration of contaminants in groundwater. A weight-of-evidence approach was used for this evaluation.

- The primary line of evidence that attenuation is occurring at a site is reduction over time in contaminant concentrations or mass, or both. Explosives were detected above their site characterization PALs in only three shallow bedrock monitoring wells during the latest sampling events (JAW-627, NBPLF-MW4, and NBPLF-MW6), east of the former landfill. RDX concentrations at JAW-627 have been increasing since 2001 (Figure 5.4-1). The highest concentrations of RDX were detected at this well during the most recent monitoring event, in 2018 (Figure 5.4-1). This increase in concentrations may indicate that residual contamination is present at the site that is providing a source to this plume, or that the plume has migrated. The other two monitoring wells with exceedances, NBPLF-MW4 and NBPLF-MW6, were installed in 2020 and do not have trend data available. Nevertheless, concentrations in these two wells were low (< 5 µg/L), and the lack of RDX exceedances in adjacent monitoring wells (overburden well JAW-626 and deep bedrock well NBPLF-MW3) samples suggests that any plume migration is limited.
- Most anaerobic daughter products of RDX were nondetected at NBPLF in 2018 through 2020. However, low levels (< 2 µg/L) of MNX were detected at monitoring wells NBPLF-MW4 and NBPLF-MW6 in 2020, providing evidence that anaerobic biodegradation of RDX may be occurring at the NBPLF.
- Water quality parameters can be used to evaluate whether the geochemical conditions are conducive to biodegradation. During the current RI, groundwater in the impacted monitoring wells in the RDX plume (JAW-627, NBPLF-MW4, and NBPLF-MW6) were observed to be under aerobic and oxidizing conditions, except at NBPLF-MW3, a deep bedrock monitoring well where low DO and negative ORP were observed. DO concentrations were reported in groundwater between 2.09 and 7.39 mg/L and ORP values were reported generally above +65 mV (Tables 5.1-5). pH values were relatively neutral (between 6 and 7), which is favorable for biological activity. Under these geochemical conditions, anaerobic biodegradation of explosives, particularly RDX, would be less favorable. However, the presence of an anerobic RDX daughter product (MNX) indicates that anaerobic biodegradation has occurred to some level. RDX is also subject to abiotic degradation.
- The physical natural attenuation processes are also likely helping to stabilize the plumes, given the limited extent and small size of the plumes. While the RDX in groundwater has moderate solubility and relatively low sorption potential, it should be retarded somewhat as it sorbs to the clay geology. The decreasing thickness of the overburden aquifer in this eastern portion of the site may also be a factor that is limiting plume migration. RDX has limited volatility (Table 4.2-1) and therefore is unlikely to volatilize into soil gas at the water table interface.

5.4.6 Human Health Risk Assessment

An HHRA was prepared for the NBPLF to evaluate potential current and future health risks and hazards from exposure to chemicals in site groundwater. Soil media within the NBPLF is not included in the HHRA as it is not a component of this RI; soil is addressed under the remedy for OU-1 (IAAP-037) (Leidos, 2018). A brief summary of OU-1 soil COCs is provided in Section 5.4.1.3 and historical remedial activities for soil are presented in Table 5.4-1. The NBPLF is open to recreational activities and hunting is permitted within the site boundary. However, there are no perennial surface water features within the NBPLF.

The NBPLF HHRA was conducted in accordance with the final UFP-QAPP (CH2M, 2017a), with the exception of some deviations that were agreed to during meetings or correspondence with USACE and USEPA following approval of the final UFP-QAPP. The approach and methods used to conduct the HHRA are provided in Section 4.3.1. This section presents the CEM for the NBPLF and provides the results of the four-step evaluation process comprising the following:

- Data evaluation.
- Exposure assessment.
- Toxicity assessment.
- Risk characterization.

The results of the HHRA are used to determine whether further action is warranted for groundwater at the NBPLF.

5.4.6.1 Conceptual Exposure Model

A description of the NBPLF, its operational history, previous investigations, and remedial actions are provided in Sections 5.4.1 and 5.4.2.

The NBPLF is located approximately 800 feet north of the NBPs and consists of a former landfill measuring 60 by 470 feet that was capped with clay during cleanup operations in 1980 (ECC, 2000). One building, BG-199-4, is present at the NBPLF and is currently used as a breakroom for AO staff. Additional activities at this site include waste disposal in dumpsters of slightly contaminated explosives-contaminated waste approved by USEPA (USEPA, 1983, 2001c) and RCRA 90-day hazardous waste storage of paint filters (contaminated with aluminum epoxy paint), which are shipped offsite for disposal at approved facilities (USEPA, 2018a). Culverts are not present at the site; therefore, potential groundwater exposures by future construction/utility workers are not complete at the NBPLF.

Groundwater is not currently being used as a potable water source, and there are no plans to use groundwater for potable purposes in the future; however, based on applicable CERCLA policy and guidance, groundwater at the NBPLF is classified as Class IIB, a potential source of drinking water (USEPA, 1989). Therefore, the HHRA for the NBPLF evaluates potential exposures to groundwater due to its potential future use as a drinking water source. This consists of the evaluation of future residential exposures to groundwater.

The following potential current and future human receptors were identified in the HHRA for the NBPLF:

- **Current Site Workers.** Current site workers could be exposed to indoor air (if volatile chemicals are present in groundwater and migrate to indoor air) in Building BG-199-4.
- **Future Site Workers.** Future site workers could contact groundwater based on potential future use as a drinking water source at the NBPLF and could be exposed to indoor air (if volatile chemicals are present in groundwater and migrate to indoor air) in buildings.
- **Future Hypothetical Residents.** Future hypothetical residents could contact groundwater based on potential future use as a drinking water source at the NBPLF and could be exposed to indoor air (if volatile chemicals are present in groundwater and migrate to indoor air) in buildings.

As discussed in Section 4.3.1, potential exposures and risks and hazards to site workers are estimated in the HHRA only if the estimated risks and hazards for a hypothetical residential scenario exceed acceptable risk levels and COCs are identified for a residential scenario. The human health CEM presenting potential exposure media, exposure points, receptors, and exposure routes is provided in Appendix A-5, Attachment 1 (Table 1), and depicted graphically on Figure 5.4-2.

5.4.6.2 Data Evaluation

Data Used in the HHRA

Historical groundwater samples collected from 1997, 2003, and 2004 and recent groundwater samples from 2018 to 2020 were used in the HHRA for the NBPLF. The groundwater samples collected in 1997, 2003, and 2004 were retained for metals analysis (only) since those samples were the most current metal analysis available. Samples from 2018 to 2020 were analyzed for explosives. One VOC (chloroform) was detected once in a 1995 sampling event at a concentration (0.71 µg/L) greater than the current tap water RSL (0.22 µg/L [USEPA, 2023a]), but no VOCs were detected in the 1997 sampling event, and there have been no historical detections of SVOCs, pesticides, PCBs, or PAHs at the NBPLF. Historical explosives data were not used in the HHRA since more current and representative data were collected from 2018 to 2020. Although some of the remaining data selected for the watershed-based ERA are older, this older data is still considered acceptable for use. As stated in the UFP-QAPP (CH2M, 2017), "Older data (i.e., data collected prior to 2012) may be used in the human health risk assessments if they are still representative of the site (i.e., groundwater flow is slow), chemicals have properties where there would not be a significant reduction in concentrations over time (e.g., metals), or data are conservative for site conditions." The NBPLF is generally not active, as described in Section 5.4.1. Potential soil sources to groundwater have been remediated, as described in Section 5.3.1.3. Due to a lack of continuing sources, historical concentrations in groundwater are expected to have remained stable or even decreased due to natural attenuation processes. Therefore, the assumptions in the final UFP-QAPP still hold. Samples collected prior to 2012 are considered representative of, or more conservative than, current conditions at the NBPLF.

A total of 14 groundwater samples were used to evaluate potential exposures for both a potable use scenario and the VI pathway. The groundwater samples were not collected at multilevel wells; therefore, a separate data grouping (based on shallow groundwater only) was not used to evaluate the VI pathway.

A summary of the number of chemicals analyzed and detected in groundwater is presented below:

Chemical Group	Number of Chemicals Analyzed	Number of Chemicals Detected
Groundwater		
Explosives	17	3
Metals	23	17

A description of the data groupings and samples included in the HHRA are provided in Tables 5.4-3 and 5.4-4, respectively. The analytical dataset used in the HHRA is included as Appendix A-5, Attachment 2. The groundwater sampling locations included in the HHRA are depicted on Figure 5.1-11.

Screening Results for Site-related Chemicals of Potential Concern and Naturally Occurring Chemicals

The approach and SLs used to select the COPCs (site-related COPCs or naturally occurring chemicals) are described in Section 4.3.1. The results of the COPC screening process for a hypothetical resident potentially exposed to groundwater are provided in Appendix A-5, Attachment 1 (Tables 2.1 and 2.2). The COPCs (site-related COPCs or naturally occurring chemicals) identified in site groundwater are summarized in the tables below.

Summary of COPCs for the NBPLF—Site-Related

Receptor	COPC	Frequency of Detections	Minimum Detection (µg/L)	Maximum Detection (µg/L)
Groundwater Used for Tap Water				
Future Hypothetical Resident	RDX	4 / 7	0.27	14
	Antimony	1 / 1	4.1	4.1

Summary of COPCs for the NPBLF—Naturally Occurring Chemicals

Receptor	COPC	Frequency of Detections	Minimum Detection (µg/L)	Maximum Detection (µg/L)
Groundwater Used for Tap Water				
Future Hypothetical Resident	Cadmium	3 / 5	0.56	0.93
	Chromium	5 / 5	1.0	5.23

5.4.6.3 Exposure Assessment

Although there is no burning/active landfill onsite, the NBPLF has one onsite building (BG-199-4), which is used as a breakroom by AO staff; in addition, dumpsters onsite are used for slightly contaminated explosives waste (as approved by USEPA), and there is an accumulation area for RCRA 90-day hazardous waste storage of paint filters, which are shipped offsite to an approved facility for destruction. The NBPLF is open to recreational activities, and hunting is permitted within the site boundary; however, there are no perennial surface water features within the NBPLF.

As previously discussed, groundwater is not currently being used as a potable water source; however, the HHRA for the NBPLF evaluated potential exposures to groundwater due to its potential future use as a drinking water source. This consists of the evaluation of future site worker and residential exposures to groundwater. Therefore, ingestion, dermal contact, and inhalation exposures to COPCs in groundwater were estimated for future hypothetical residents (and site workers, if applicable); inhalation exposures of COPCs in indoor air from vapor intrusion of groundwater were not evaluated at the NBPLF since no vapor intrusion COPCs were identified (Appendix A-5, Attachment 1, Table 2.2). Culverts are not located at the NBPLF; therefore, potential ingestion, dermal contact, and inhalation exposures to shallow groundwater in a trench are incomplete for future construction/utility workers. As noted previously, risks and hazards for site workers are estimated only if the estimated risks or hazards for a hypothetical residential scenario exceed acceptable risk or hazard levels, and COCs are identified for a residential scenario. The potential exposure pathways quantified in the HHRA are indicated in Appendix A-5, Attachment 1 (Table 1), and on Figure 5.4-2. The following receptor scenario was quantified in the HHRA for the NBPLF:

- Future hypothetical residents (adult and child).
  - Groundwater (tap water) COPCs—ingestion and dermal contact.

Risks and hazards for site workers and construction/utility workers were not quantified in the HHRA because the estimated risks or hazards for a hypothetical residential scenario did not exceed acceptable risk or hazard levels and COCs were not identified for a residential scenario.

In accordance with USEPA guidance *Determining Groundwater Exposure Point Concentrations, Supplemental Guidance* (USEPA, 2014b), groundwater EPCs are typically calculated based on the data collected in the core of a plume. Two RDX plumes were historically present at the NBPLF (Figure 5.4-4); however, RDX was detected only at the eastern plume during the 2018–2020 RI activities. Two monitoring wells (NBPLF-MW3 and JAW-627) are located within the core of the plume; two groundwater samples are available in the HHRA data set for the RDX plume. If the maximum detected concentration of a groundwater COPC was not in the subset of wells from the core of the RDX plume, the maximum detected concentration of the COPC in the sitewide groundwater data set was used as the EPC.

For groundwater, where a sufficient number of samples and detected concentrations are available for COPCs, the UCL on the mean is selected as the EPC. For COPCs where fewer than eight samples or four detects were available, the maximum detected concentrations were selected as the EPCs. For antimony, cadmium, and chromium, the maximum detected concentrations were located outside of the RDX plume and were used as the EPCs. The groundwater EPCs used to estimate the chemical intakes for groundwater are provided in Appendix A-5, Attachment 1 (Table 3.1).

The exposure factors used in the intake calculations for receptor scenarios are included in Appendix A-5, Attachment 1 (Table 4.1). The primary references for the exposure factor values are the standard default exposure factors presented in the HHEM (USEPA, 2014a).

5.4.6.4 Toxicity Assessment

The oral toxicity values (CSFs and RfDs) used in the HHRA were obtained from the USEPA standard hierarchy of toxicity value sources (USEPA, 2003b), as provided in Section 4.3.1. Noncancer toxicity values for the COPCs identified at the NBPLF are provided in Appendix A-5, Attachment 1 (Table 5.1). Cancer toxicity values for the COPCs are provided in Appendix A-5, Attachment 1 (Table 6.1).

One COPC (chromium, evaluated as hexavalent chromium in the HHRA) was identified as acting with an MMOA. The ADAFs and exposure assumptions used to calculate adjusted intakes and exposure concentrations for chromium are provided in Appendix A-5, Attachment 1 (Table 4 Supplement).

5.4.6.5 Risk Characterization

The risk characterization for the NBPLF was completed using a four-step process, as discussed in Section 4.3.1. The results of each step are discussed below.

Step 1: Total Combined Risks and Hazards from Site-related COPCs and Naturally Occurring Chemicals

Step 1 consists of calculating receptor-specific ELCRs and HIs that include contributions from both site-related COPCs and naturally occurring chemicals. The estimated risks and hazards for a hypothetical residential scenario are summarized in Table 5.4-5.

Table 5.4-5. Summary of Total Combined Risk and Hazard Estimates for Site-Related COPCs and Naturally Occurring Chemicals—IAAP-037G: North Burn Pads Landfill Groundwater
Iowa Army Ammunition Plant, Middletown, Iowa

Receptor [a]	ELCR/HI Tables (RME) in Appendix A-5, Attachment 1	Exposure Medium	COPC/Chemical	NBPLF		
				EPC [b]	ELCR	HI
Hypothetical Resident (Adult)	7.1 and 9.1	Groundwater (Tap Water)	RDX	14	NA	0.1
			Antimony	4.1	NA	0.3
			Cadmium	0.93	NA	0.3
			Chromium (hexavalent)	5.23	NA	0.08

Table 5.4-5. Summary of Total Combined Risk and Hazard Estimates for Site-Related COPCs and Naturally Occurring Chemicals—IAAP-037G: North Burn Pads Landfill Groundwater
Iowa Army Ammunition Plant, Middletown, Iowa

Receptor [a]	ELCR/HI Tables (RME) in Appendix A-5, Attachment 1	Exposure Medium	COPC/Chemical	NBPLF EPC [b]	NBPLF ELCR	NBPLF HI
			Total HI (Groundwater—Tap Water):		**NA**	**0.8**
Hypothetical Resident (Child)	7.2 and 9.2	Groundwater (Tap Water)	RDX	14	NA	0.2
			Antimony	4.1	NA	0.5
			Cadmium	0.93	NA	0.5
			Chromium (hexavalent)	5.23	NA	0.1
			Total HI (Groundwater—Tap Water):		**NA**	**1**
Hypothetical Resident (Adult/Child Aggregate)	7.3 and 9.3	Groundwater (Tap Water)	RDX	14	1E-05	NA
			Antimony	4.1	NA	NA
			Cadmium	0.93	NA	NA
			Chromium (hexavalent)	5.23	1E-04	NA
			Total ELCR (Groundwater—Tap Water):		**2E-04**	**NA**

Notes:

µg/L = microgram per liter

COPC = chemical of potential concern

ELCR = excess lifetime cancer risk

EPC = exposure point concentration

HI = hazard index

NA = not applicable

RME = reasonable maximum exposure

[a] ELCRs were estimated for the adult/child aggregate receptor based on lifetime exposure and noncarcinogenic HIs were estimated separately for adult and child residents.

[b] EPC Units: groundwater (tap water) - µg/L

Step 2: Risk Characterization of Naturally Occurring Chemicals

Step 2 consists of calculating receptor-specific ELCRs and HIs for naturally occurring chemicals. Two COPCs (cadmium and chromium) were identified as naturally occurring or not site-related chemicals in site groundwater at the NBPLF, as discussed in Section 5.4.4.2. The maximum detected concentrations of cadmium and chromium were less than their respective BTVs. The estimated risks and hazards for the naturally occurring chemicals in groundwater for a future hypothetical residential scenario are provided in Table 5.4-6. The naturally occurring chemicals are not used to identify the final COCs for the NBPLF and are not discussed further in the HHRA after this step.

Table 5.4-6. Summary of Risk and Hazard Estimates for Naturally Occurring Chemicals— IAAP-037G: North Burn Pads Landfill Groundwater
Iowa Army Ammunition Plant, Middletown, Iowa

Receptor [a]	ELCR/HI Tables (RME) in Appendix A-5, Attachment 1	Exposure Medium	COPC/Chemical	NBPLF		
				EPC [b]	ELCR	HI
Hypothetical Resident (Adult)	7.4 and 9.4	Groundwater (Tap Water)	Cadmium	0.93	NA	0.3
			Chromium (hexavalent)	5.23	NA	0.08
			Total HI (Groundwater—Tap Water):		**NA**	**0.4**
Hypothetical Resident (Child)	7.5 and 9.5	Groundwater (Tap Water)	Cadmium	0.93	NA	0.5
			Chromium (hexavalent)	5.23	NA	0.1
			Total HI (Groundwater—Tap Water):		**NA**	**0.6**
Hypothetical Resident (Adult/Child Aggregate)	7.6 and 9.6	Groundwater (Tap Water)	Cadmium	0.93	NA	NA
			Chromium (hexavalent)	5.23	1E-04	NA
			Total ELCR (Groundwater—Tap Water):		**1E-04**	NA

Notes:

COPC = chemical of potential concern

ELCR = excess lifetime cancer risk

EPC = exposure point concentration

HI = hazard index

NA = not applicable

RME = reasonable maximum exposure

μg/L = microgram per liter

[a] ELCRs were estimated for the adult/child aggregate receptor based on lifetime exposure and noncarcinogenic HIs were estimated separately for adult and child residents.

[b] EPC Units: groundwater (tap water) - μg/L

Step 3: Risk Characterization of Site-related COPCs

Step 3 consists of calculating receptor-specific ELCRs and HIs associated with site-related COPCs. One metal (antimony) and one explosive (RDX) were identified as site-related COPCs for groundwater at the NBPLF. The estimated risks and hazards for RDX in groundwater for a hypothetical resident are provided in Table 5.4-7.

Table 5.4-7. Summary of Risk and Hazard Estimates for Site-Related COPCs— IAAP-037G: North Burn Pads Landfill Groundwater
Iowa Army Ammunition Plant, Middletown, Iowa

Receptor [a]	ELCR/HI Tables (RME) in Appendix A-5, Attachment 1	Exposure Medium	COPC/Chemical	NBPLF		
				EPC [b]	ELCR	HI
	7.7 and 9.7	Groundwater	RDX	14	NA	0.1

Table 5.4-7. Summary of Risk and Hazard Estimates for Site-Related COPCs— IAAP-037G: North Burn Pads Landfill Groundwater

Iowa Army Ammunition Plant, Middletown, Iowa

Receptor [a]	ELCR/HI Tables (RME) in Appendix A-5, Attachment 1	Exposure Medium	COPC/Chemical	NBPLF		
				EPC [b]	**ELCR**	**HI**
Hypothetical Resident (Adult)		(Tap Water)	Antimony	4.1	NA	0.3
			Total HI (Groundwater—Tap Water):		**NA**	**0.4**
Hypothetical Resident (Child)	7.8 and 9.8	Groundwater (Tap Water)	RDX	14	NA	0.2
			Antimony	4.1	NA	0.5
			Total HI (Groundwater—Tap Water):		**NA**	**0.7**
Hypothetical Resident (Adult/Child Aggregate)	7.9 and 9.9	Groundwater (Tap Water)	RDX	14	1E-05	NA
			Antimony	4.1	NA	NA
			Total ELCR (Groundwater—Tap Water):		**1E-05**	**NA**

Notes:

COPC = chemical of potential concern

ELCR = excess lifetime cancer risk

EPC = exposure point concentration

HI = hazard index

NA = not applicable

RME = reasonable maximum exposure

μg/L = microgram per liter

[a] ELCRs were estimated for the adult/child aggregate receptor based on lifetime exposure and noncarcinogenic HIs were estimated separately for adult and child residents.

[b] EPC Units: groundwater (tap water) - μg/L

Step 4: Final COC Determination

The total ELCRs and HIs estimated for groundwater based on a future hypothetical residential scenario (adult and child) did not exceed USEPA's acceptable risk range of 1×10^{-6} to 1×10^{-4} and target organ HI of 1. Therefore, no COCs were identified for groundwater at the NBPLF, and the NBPLF qualifies for an NFA decision for groundwater based on the results of the HHRA.

5.4.6.6 Uncertainty Analysis

The assumptions used in the HHRAs have inherent uncertainty. The general uncertainties associated with the HHRAs for the sites in this RI report are provided in Section 4.3.1. This section provides additional site-specific uncertainties associated with the HHRA for the NBPLF that are not included in Section 4.3.1.

Total chromium was initially identified as a COPC in groundwater because the maximum detected concentration for total chromium exceeded the tap water RSL for hexavalent chromium. It is likely that some or all of the total chromium concentrations are in the trivalent chromium form. All of the groundwater chromium concentrations are less than the tap water RSL for trivalent chromium and the MCL and BTV for total chromium. Using the hexavalent chromium RSL to evaluate total chromium in the COPC selection process was a conservative approach in the HHRA. Total chromium was determined to be naturally occurring in groundwater at the NBPLF.

The maximum RL of detected chemicals not identified as COPCs in the RAGS Table 2 Series (Appendix A-2, Attachment 1) was compared to their RSL. However, chemicals whose RL exceeds the RSL were not identified as COPC. For the NBPLF, silver's RL exceeded its RSL. Although the RLs for this detected chemical is greater than the RSL, further consideration of this detected chemical does not appear warranted in the NBPLF HHRA.

Chemicals that were 100 percent not detected in groundwater were not included in the COPC identification process; however, they were evaluated in a separate screening to determine if elevated nondetected results were present in groundwater. The detailed analysis of the nondetected chemicals at the NBPLF is provided in Appendix A-5, Attachment 3. In summary, four nondetected explosives (2,4-dinitrotoluene, 2,6-dinitrotoluene, 2-nitrotoluene, and nitrobenzene), and three nondetected metals (arsenic, cobalt, and thallium) have DLs and/or RLs exceeding SLs at the NBPLF. Although the DLs and/or RLs for these nondetect chemicals are greater than the SLs, based on the acceptably low DLs, further consideration of nondetect chemicals does not appear warranted in the NBPLF HHRA.

5.4.6.7 Summary of HHRA

An HHRA was prepared for the NBPLF to evaluate potential current and future health risks from exposure to chemicals in site groundwater. Although there is no burning/active landfill onsite, the NBPLF is an active site, and a building (BG-199-4) is present. The only current activity at NBPLF is use of BG-199-4 as a breakroom for AO staff, the use of dumpsters for slightly contaminated explosives waste (as approved by USEPA), and as an accumulation area for RCRA 90-day hazardous waste storage of paint filters, which are shipped offsite to an approved facility for destruction. The NBPLF is open to recreational activities and hunting is permitted within the site boundary; however, there are no perennial surface water features within the NBPLF. Soil is addressed under the remedy for OU-1 (IAAP-012) (Leidos, 2018).

The following potential human receptors were identified in the HHRA for the NBPLF:

- **Current Site Workers.** There are no complete exposure pathways for current site workers since volatile chemicals were not detected in NBPLF groundwater.
- **Future Site Workers.** Future site workers could contact groundwater based on potential future use as a drinking water source at the NBPLF.
- **Future Hypothetical Residents.** Future hypothetical residents could contact groundwater based on potential future use as a drinking water source at the NBPLF.

Potential exposures and risks and hazards to future site workers were not estimated in the HHRA since estimated risks and hazards for a hypothetical residential scenario did not exceed acceptable risk and hazard levels and no COCs were identified for a residential scenario.

The COPCs (site-related COPCs or naturally occurring chemicals) identified in site groundwater are as follows:

- Groundwater (potable use):
  - Naturally occurring: cadmium and chromium.
  - Site-related: antimony and RDX.

The risk characterization for the NBPLF was completed using a four-step process, as discussed in Section 4.3.1. Step 1 presents the total combined risks and hazards from site-related COPCs and naturally occurring chemicals, as summarized in Table 5.4-5. Step 2 presents the risks and hazards from naturally occurring chemicals, as summarized in Table 5.4-6. Step 3 presents the risks and hazards from site-related COPCs, as summarized in Table 5.4-7.

No unacceptable groundwater risks or hazards were identified in Step 3 for hypothetical residents. Therefore, in Step 4, no COCs were identified for groundwater at the NBPLF, and the NBPLF site qualifies for an NFA decision for groundwater based on the results of the HHRA.

5.4.7 Ecological Risk Assessment

The ERA for groundwater at the NBPLF is presented herein, beginning with Step 1 of the ERA process (to determine whether there are complete exposure pathways). Soil at the NBPLF is already addressed under the remedy for OU-1. There are no perennial surface water features within the NBPLF boundary; however, Spring Creek is present to the east of the NBPLF. A summary of the ERA conclusions for Spring Creek and its perennial tributaries is provided in the ERA for the WBPA (Section 5.2.7).

Groundwater is present onsite, but ecological receptors are not exposed directly to groundwater; nevertheless, groundwater is a transport medium, and contaminated groundwater has the potential to migrate to and discharge to surface water bodies. There is a lack of perennial surface water bodies on the NBPLF. Therefore, the groundwater-to-surface-water exposure pathway is incomplete. There are no complete exposure pathways for ecological receptors on the site. Therefore, there are no adverse effects identified and no additional actions are required from an ecological perspective.

5.4.8 Conclusions and Recommendations

An RI was conducted for the NBPLF to refine the nature and extent of contamination in groundwater from historical activities and assess for potentially unacceptable risk to human health and adverse effects to the environment. Analytical data available for groundwater at NBPLF includes data for explosives, VOCs, SVOCs, PAHs, radionuclides, and metals. Of these, explosives and metals were identified as site-related chemicals of interest based on historical site operations and a comparison of concentration data to site characterization PALs and BTVs (See Section 4.1).

In groundwater, no VOCs or metals were detected above their site characterization PAL or BTV (if available) during the most recent sampling events, aside from antimony, which exceeded the BTV at monitoring well JAW-626 in 2004 but was below the PAL. Only one explosive (RDX) was detected above its site characterization PAL during the 2018–2020 RI sampling events. RDX contamination has been observed as two small plumes at the NBPLF. The largest plume is located along the eastern boundary of the site within the overburden aquifer. The second RDX plume is isolated and was historically defined by former overburden well JAW-625. However, RDX was not detected in nearby NBPLF-MW1 during the current RI (2018–2020). Therefore, RDX concentrations in this second plume may have attenuated below the site characterization PAL. The soil removal that was completed in 1998 is assumed to have removed the bulk of RDX contamination that could be a source to groundwater. Confirmation sampling showed one RDX concentration (2.5 mg/kg) above the OU-1 leachability-based RG (1.3 mg/kg) within the former NBPLF. The increasing RDX concentrations at JAW-627 indicate there may still be a source of RDX leaching to groundwater from the former landfill. Increasing RDX concentrations may also be indicative of continued plume migration.

An HHRA and an ERA were conducted to quantify potential risks and hazards to human health and the environment from exposure to contaminants at the NBPLF. The following conclusions were made based on the risk assessments:

- The HHRA concluded that there are no unacceptable risks or hazards for hypothetical residents from exposure to groundwater at the NBPLF.
- The ERA concluded that there are no adverse effects to ecological receptors identified and no additional actions are required from an ecological perspective.

Based on the results of the RI and risk assessments, NFA appears to be warranted for groundwater at the EBPs. However, given the increasing RDX concentrations in groundwater at JAW-627, and the fact that not all RDX in soil was removed at this site to the OU-1 leachability RG, additional groundwater monitoring is recommended at JAW-627 as part of a Supplemental Remedial Investigation (SRI). The additional groundwater data from an SRI can be used as a further line of evidence that NFA is warranted for the NBPLF.

5.5 Fire Training Pit—Groundwater (IAAP-039G)

This subsection summarizes RI activities at the FTP site within the EDA and documents the RI for groundwater at the FTP (IAAP-039G). Soil is addressed under the remedy for OU-1 (IAAP-039) (Leidos, 2018). There are no perennial surface water features within the FTP site boundary; however, Spring Creek flows adjacent to several environmental sites within the EDA (Figure 5.1-1). Because the largest portion of Spring Creek and perennial tributaries are present within the WBPA site boundary, risk assessment of surface water and sediment will be evaluated under that IAAAP site (IAAP-032G) and presented in Section 5.2.

The FTP was identified as an area of potential interest (AOPI) during a Preliminary Assessment for per- and polyfluoroalkyl substances (PFAS) at IAAAP (Arcadis, 2020). As documented in the final *Fourth Five-Year Review Report for IAAAP* (USACE and Dawson, 2021), historical activities at the FTP were performed during the period of known use of aqueous film-forming foam by the military for firefighting training. The U.S. Army is evaluating IRP sites for perfluorooctanoic acid (PFOA), perfluorobutanesulfonic acid (PFBS), and perfluorooctanesulfonic acid (PFOS) contamination and is following Department of Defense and Army guidance and policy regarding these emerging chemicals. The PFAS AOPIs are currently under a site inspection. The evaluation of PFOS, PFBS, and PFOA at the FTP has not been completed and, therefore, PFAS is not a component of this OU-10 RI.

5.5.1 Background

5.5.1.1 Site Description

The FTP is an inactive site in the northeast portion of the IAAAP facility (Figure 5.1-1). The FTP site boundary encompasses approximately 2 acres. The FTP is part of a larger area, the EDA.

The FTP area includes a former smoke trainers vault (Building 200-30), two former burn pits southeast of the smoke trainers vault, and a former disposal pit between the smoke trainers vault and the burn pits.

5.5.1.2 Operational History

The FTP was built in the early 1970s and consisted of an unlined, open depression that measured approximately 40 feet wide, 16 feet long, and 2 feet deep (Tetra Tech, 2006, 2012). A crescent-shaped berm approximately 3 feet high was present around the northern and western boundaries of the pit (JAYCOR, 1996). This pit was used for firefighting training operations between 1982 and 1987. Fire-extinguishing training procedures included setting 55-gallon drums filled with solvents and fuels on fire and then subsequently extinguishing them. Installation personnel do not have records explicitly stating aqueous film-forming foam was used for this training; however, a previous document referenced foams that were used to extinguish these fires (URS, 2004c). Waste solvents were reportedly used from 1982 to 1984, and fuels were reportedly used from 1984 to 1987. Water from the fire-extinguishing exercises, in addition to old paint, was also disposed of at the FTP. Based on summaries of previously conducted interviews (Tetra Tech, 2006), wastes burned at the FTP were typically generated at one of the load lines and were not stored in the FTP area. Fire training activities at the FTP were discontinued in 1988.

Two smaller pits existed north of the main training pit, discussed above. One disposal pit, northwest of the FTP, contained trash and debris, and another burn pit, northeast of the FTP, was used to burn wastes similar to those used in the firefighting practices in the main pit, though this northeast disposal pit was not used for firefighter training. At this pit, trucks reportedly would unload liquid wastes, approximately two or three 55-gallon drums' worth at a time, directly to the pit onto hay bales that were then ignited and allowed to burn. This northeast pit was reportedly used during the same period as the main training pit.

The former smoke trainers vault (Building 200-30) was used from 1982 to 1987 during firefighting sessions (JAYCOR, 1996). According to IAAAP personnel, only scrap wood and wooden pallets were burned here (URS, 2004c).

Operational activities were also conducted in buildings or igloos outside the FTP site boundary. Building BG-2,southeast of the FTP site boundary, was used as a laboratory in the 1940s and 1950s and was then converted to an explosives-holding building in the 1990s. Storage igloos BG-3, BG-4, BG-5, and BG- 12 were reportedly used to store explosives, which were moved from the igloos to the Explosive Waste Incinerator (EWI) for incineration (URS, 2004c). Storage igloos BG-3 through BG-5 have recently been demolished.

5.5.1.3 Previous Investigations and Remedial Actions

Numerous investigations have been conducted at IAAAP since the 1980s. Table 5.5-1 summarizes the previous investigations and remedial actions conducted at the FTP, including conclusions and recommendations. Although soil at FTP has already been addressed under OU-1, previous investigations for soil are also presented in Table 5.5-1 to support the CSM.

This report summarizes the RI for groundwater at the FTP (IAAP-039G). Previous investigations pertinent to the RI for groundwater are listed below; additional details on these investigations (including a more detailed description of work completed, as well as work not pertinent to this RI), are included in Table 5.5-1. Previous groundwater sampling locations are shown on Figure 5.1-2.

Investigation	Conclusion
Facility-wide Preliminary Assessment (JAYCOR, 1994)	The Preliminary Assessment indicated that while no evidence had been found at the FTP, no specific contamination study had been performed in this area. Because the Preliminary Assessment indicated there was a potential for contamination at the EDA, it was recommended that the extent of contamination in the vicinity of the EDA should be confirmed, and surface water and groundwater contaminant migration should be investigated.
Facility-wide Site Inspection (JAYCOR, 1992)	No groundwater samples were collected at the FTP during the SI. Further investigation was recommended as part of the RI.
Phase I and Follow-on Remedial Investigation (JAYCOR, 1993, 1996)	Six newly installed piezometers (R27-PZ-01 through R27-PZ-06) were sampled for metals, VOCs, and SVOCs during Phase I. Eight new monitoring wells were installed and sampled for VOCs, SVOCs, and metals during Phase II and follow-on RI activities. In groundwater, VOCs and SVOCs were the main contaminants observed at the FTP, and metals contamination was present to a lesser extent. The RI recommended semiannual compliance groundwater monitoring at three wells in the FTP for VOCs, SVOC, and metals.
Periodic Groundwater and Surface Water Monitoring (multiple reports)	Periodic groundwater sampling was conducted at the FTP between the 1994 and 2004 as part of the FFA compliance monitoring and groundwater monitoring program. Samples were analyzed for VOCs, SVOC, explosives, metals, radionuclides, and/or natural attenuation parameters. Numerous VOCs associated with chlorinated solvents, breakdown products of solvents, and fuels in excess of screening levels were detected in groundwater. Two compounds, 1,1-DCA and 1,1-DCE, exceeded with the greatest frequency and over the largest extent. The highest concentrations of VOCs were noted to be generally in the area of the former excavation, screened across sand that was intentionally placed at the bottom of the excavation. Some wells exhibited exceedances of metals, particularly manganese and iron. RDX was consistently detected above screening criteria at one well, FTA-99-1.

Investigation	Conclusion
Supplemental Groundwater Remedial Investigation (MWH, 2001)	In 1997, groundwater samples were collected from eight existing monitoring wells and analyzed for VOCs, SVOCs, explosives, and metals. VOCs, primarily 1,1-DCE and PCE, exceeded screening levels at six locations and two locations contained SVOCs above screening levels. No metals or explosives contamination was detected at the FTP. It was concluded that VOC contamination was present in both shallow and bedrock, however no deeper wells were present in the area to provide vertical delineation. Additional horizontal delineation was also warranted to the southeast of the FTP.
Additional Monitoring Well Installation (Harza, 2000)	Three new wells were installed. One 6-inch sump well (SA-99-1) was installed within the former pit area and two monitoring wells (shallow overburden and bedrock wells) were installed downgradient of the excavation area. The wells were added to the groundwater monitoring program.
Feasibility Study Data Collection (URS, 2004c)	Groundwater samples were collected from 26 DPT borings and analyzed for VOCs and/or explosives. Groundwater samples were also collected from eight new monitoring wells and analyzed for explosives, metals, VOCs, and natural attenuation parameters. VOCs were detected in DPT and monitoring well groundwater samples. Explosives were detected in one DPT sample and two well samples. Arsenic was also detected above screening criteria at the SA-99-1 well. Risk assessments were conducted using the groundwater data collected during the Feasibility Study investigation and the groundwater and surface water data collected during the periodic, compliance, monitoring events. VOCs, explosives, and arsenic were identified as a groundwater COCs while there were no COCs identified for surface water for the commercial/industrial worker. Groundwater flow and contaminant fate and transport models were developed. The models predicted that VOC concentrations in groundwater should continue to decline over time due to naturally occurring processes. The initial natural attenuation concluded that natural attenuation processes may be occurring in the FTP plume, particularly within the source area.
Groundwater Treatability Study (Tetra Tech, 2010)	A groundwater treatability study was conducted at the FTP to test the efficacy of in situ bioremediation at reducing the high chlorinated VOC contamination. High-fructose corn syrup solutions were injected into five DPT injection points between 2005 and 2006. Six monitoring wells were monitored during the study. It was concluded that high-fructose corn syrup fostered fermentation; however, concentrations of PCE, TCE, and 1,1,1-TCA increased in the study area. Approximately 30 feet from the FTP, PCE concentrations remained stable. TCE, 1,1,1-TCA, and 1,1-DCE concentrations began to decrease after an initial increase, but in some instances, 2010 results were higher than baseline concentrations.
Comprehensive Watersheds Evaluation and Supplemental Data Collection Work Plan (Tetra Tech, 2006)	The work plan concluded that no groundwater, surface water, or sediment data gaps were present at the FTP.

PCE = tetrachloroethylene

As part of the previous investigations under OU-1, explosives, VOCs, SVOCs, pesticides, PCBs, and metals were identified as soil COCs for the EDA (ECC, 2000). Elevated levels of VOCs, SVOCs, metals, and polynuclear aromatic compounds were identified in soil at the FTP. To address risks and hazards associated with these COCs, soil removal actions have been conducted at the FTP and LUCs have been implemented (Leidos, 2019); excavation areas are shown on Figure 5.1-1. Between 1998 and 2003, approximately 6,166 cubic yards of contaminated soil was removed from excavations around the FTP.

In 1998, approximately 4,250 cubic yards of contaminated soil was removed (ECC, 2000). The soil excavation was completed in three phases up to depth of 22 feet bgs. Final confirmation samples verified that all soil COCs were removed to excavation criteria within the unsaturated zone. Final confirmation soil samples from this first removal action were below the excavation criteria. Prior to backfilling the excavation, approximately 2 to 3 feet of sand was placed along the bottom of the entire excavation for groundwater extraction (ECC, 2000), if necessary. The remainder of the excavation was backfilled with clay (ECC, 2000).

In 2003, an additional 616 cubic yards of soil contaminated with explosives and metals was removed to approximately 10 feet bgs from the former burn pit north of the main training pit. Approximately 116 cubic yards of explosives and metals contaminated soils and debris were removed to approximately 6 feet bgs from the former disposal pit between the main training pit and smoke trainers vault. Based on confirmation sampling, no soil with concentrations above OU-1 RGs remained in these excavated areas (ECC, 2005). The excavations were deemed clean for backfilling (ECC, 2005).

5.5.2 2018–2020 Remedial Investigation Activities

Additional field work was conducted at the FTP to resolve data gaps needed to complete the RI for groundwater (IAAP-039G). As documented in the final *Site-specific Worksheets for Operable Unit 6 of the Uniform Federal Policy–Quality Assurance Project Plan for Remedial Investigation at Iowa Army Ammunition Plant (Packet 2*) (CH2M, 2018a), although groundwater contamination at the FTP had been delineated, concentrations of site contamination may have changed because of source removal actions, natural degradation, and treatability study injections. Therefore, additional monitoring was warranted to understand of current conditions to complete the RI. To address this data gap, groundwater sampling was conducted at 24 existing wells at the FTP and four existing wells at the WBPA. Fieldwork at the FTP was conducted in accordance with the UFP-QAPP (CH2M 2018a).

Between March 8 and 24, 2019, groundwater samples were collected from 24 existing monitoring wells at the FTP and three existing wells at the WBPA (WBP-99-1, JAW-25, and G-30). An additional well from the WBPA (JAW-68) was sampled in December 2019. Groundwater samples were collected from all wells for analysis of VOCs by Method SW8260. Eleven of the monitoring wells at the FTP were also sampled for explosives by Method SW8330B, and 12 monitoring wells at the FTP were also sampled for metals by Method SW6020A. The four WBPA monitoring wells (WBP-99-1, JAW-25, JAW-68, and G-30) were also sampled for explosives and are discussed in Section 5.2. Monitoring wells were sampled via low-flow purging and sampling techniques. Purge logs are included in Appendix C. Data was managed and validated as discussed in Section 3.3. Laboratory reports are provided in Appendix B.

All IDW generated during activities (purge water) was disposed of in accordance with management activities discussed in Section 3.2.9. Waste management documentation is provided in Appendix D.

Six existing monitoring wells (FTA-TT-MW-01 through FTA-TT-MW-05, and FTP-UNKMW-001) were resurveyed by Bruner, Cooper, and Zuck, Inc., licensed Iowa surveyors, on December 17, 2019, since top-of-casing elevation data were not available for these wells. Survey information is included in Appendix E.

5.5.3 Environmental Setting

5.5.3.1 Topography and Surface Water

The terrain of this site gently slopes to the south and southeast. The eastern portions of the site slope toward an intermittent tributary of Spring Creek, located southeast of the FTP. Ground surface elevations range from 692 feet above mean sea level at the northern end of the FTP area to 656 feet above mean sea level at the tributary of Spring Creek. Surface runoff is channeled through ditches and culverts along the roads at the site, which direct water south and east toward an intermittent tributary of Spring Creek (Figure 5.1-1).

5.5.3.2 Geology and Hydrogeology

The geology of the FTP area consists of unconsolidated overburden overlying shale and limestone bedrock. Overburden thickness ranges from roughly 10 to 30 feet. At the FTP, it consists primary of glacial till, observed as a heterogeneous mixture of clay, silt, sand, and gravel. Discontinuous sand and gravel seams are present in some areas to a depth of 12 to 15 feet bgs (JAYCOR, 1996; Tetra Tech, 2006). Stiff clay is present in the northern portion of the site overlying the bedrock, near the former Smoke Training Vault and main training pit and is considered an aquitard based on very a low vertical hydraulic conductivity of 1.5×10^{-9} cm/sec based on laboratory Shelby tube analysis (JAYCOR, 1996). In the southern portion of the site, the stiff clay transitions to a clay containing silt and increasing amounts of sand. Bedrock in this area is described from area boring logs as coarse grained, fossiliferous limestone of the Warsaw Formation. The upper portion of the bedrock near the overburden and bedrock interface is weathered and contains fractures (JAYCOR, 1996).

Overburden groundwater at the FTP is monitored by wells with screen intervals ranging from 5 to 34 feet bgs. Groundwater was measured between 3.73 and 13.63 feet btoc during the recent 2019 gauging event; however, historically water levels have ranged between approximately 2 and 22 feet btoc. Water levels from overburden wells screened partly in a sandy layer are typically higher than levels in surrounding areas. Bedrock groundwater was measured between 10.15 and 20.25 feet btoc in 2019; however, historically bedrock groundwater has been measured up to 47.9 feet btoc.

Based on historical and recent groundwater gauging data, overburden groundwater flows semiradially towards Spring Creek (to the northeast and east) and an intermittent tributary to Spring Creek (to the southeast) (Figure 5.1-3). A groundwater high is typically present near JAW-63 and/or JAW-62; both wells are in the western portion of the FTP area. Hydraulic gradients are low, between 0.001 and 0.06 ft/ft. Bedrock groundwater flow is to the east (Figure 2-3), with historical hydraulic gradients between approximately 0.01 and 0.04 ft/ft. Downward vertical gradients were observed at well pairs FTP-MW7/FTP-MW8, JAW-60/FTP-MW4, and FTA-99-1/FTA-99-2 based on March 2019 groundwater elevation data (Table 5.1-3). Hydraulic conductivities based on slug tests range from 0.0017 to 1.7 feet per day in overburden and between 0.00042 to 0.0076 feet per day in bedrock (Tetra Tech, 2012). The higher hydraulic conductivity values in the overburden are attributed to wells partly screened within sand lenses or weathered bedrock.

5.5.4 Nature and Extent of Contamination

This subsection describes the nature and extent of groundwater contamination at the FTP area. There are no perennial surface water features present at this site. Although soil has been addressed under OU-1, a summary of the soil COCs is discussed briefly to inform the CSM for potential groundwater contaminants. The source of contamination at the FTP area is attributed to releases to the surface and subsurface as a result of historical site operations, including chemical use, burning, and debris disposal.

Groundwater samples have been collected at the FTP since 1992. Twenty-four active monitoring wells are present at the FTP. Fourteen of the wells are screened in the overburden to depths ranging from 5 to 32 feet bgs, five wells are screened across the overburden/bedrock transition zone from 5.5 to 34 feet bgs, and five are screened in shallow bedrock at depths ranging from 10.5 to 59.1 feet bgs (locations presented in Figure 5.1-2). Historical groundwater samples were analyzed for analyzed for VOCs, SVOCs, PAHs, explosives, metals, PCBs, radionuclides, and pesticides. No PCBs were detected in historical groundwater samples, and pesticides have not been detected since 1992. Based on historical site operations and COCs identified in soil, explosives, VOCs, and metals are considered chemicals of interest in groundwater at the FTP.

Samples were collected from 24 monitoring wells during the most recent RI activities, between 2018 and 2020, and analyzed for VOCs, metals, and/or explosives. Table 5.5-2 summarizes the chemicals detected in groundwater between 2000 and 2020 sampling events at the FTP. Summary tables of all the analytical results (including nondetects) from the 2018–2020 RI activities are provided in Appendix G. Summary tables of all historical analytical results from the FTP are provided in Appendix H.

VOCs

Forty-five VOCs have been detected in groundwater at the FTP since 2000 (Table 5.5-2). However, only thirteen VOCs (1,1,1-TCA, 1,1-DCA, 1,1-DCE, 1,2,4-trimethylbenzene, 1,2-dichloroethane, benzene, cis-1,2-DCE, methylene chloride, PCE, TCE, toluene, vinyl chloride, and o-xylene) exceeded their site characterization PALs during the most recent (2019) monitoring event. VOC exceedances were observed at nine monitoring wells at the FTP with the highest concentrations and greatest number of VOCs being observed in wells located at the former main training pit and the 1998 soil removal area. VOC contamination is observed as one large plume, which extends from this source area to the east and south, extending outside of the FTP site boundary (Figure 5.1-5). This plume configuration is consistent with the groundwater flow gradients (Figure 5.1-3).

- Eleven VOCs (1,1,1-TCA, 1,1-DCA, 1,1-DCE, 1,2,4-trimethylbenzene, 1,2-dichloroethane, benzene, cis-1,2-DCE, PCE, toluene, vinyl chloride, and o-xylene) were detected at FTA-TT-MW-03, near the former berm surrounding the main training pit. These 11 VOCs were also detected at their highest concentrations at this location in 2019 (Figure 5.1-5). The VOC with the highest concentration was 1,1-DCA, at 4,900 µg/L. VOC concentrations at FTA-TTMW-03 declined from concentrations detected in 2010 for all analytes analyzed for in 2019, except for 1,1-DCE, PCE, and vinyl chloride, whose concentrations increased.
- TCE exceeded its PAL (5 µg/L) at three locations (JAW-60, JAW-61, and FTA-TT-MW-02) in 2019. Concentrations of TCE exceeding the PAL ranged between 37 J µg/L and 82 µg/L in the southwest portion of the FTP.
- Methylene chloride exceeded its PAL (5 µg/L) at three locations (FTA-TT-MW-02, FTA-TT-MW-04, and SA-99-1), all within the soil removal area, the former main training pit.
- Only three VOCs (1,1-DCA, 1,1-DCE, and PCE) were detected above their PALs at monitoring wells farthest downgradient of the FTP area (JAW-80, JAW-59, and FTP-MW5).

VOC exceedances at the FTP were observed in overburden and transition monitoring wells between 5 and 35 feet bgs. No VOCs were detected above their site characterization PALs at shallow bedrock monitoring wells at the FTP. VOC concentrations were nondetect or detected below PALs at JAW-62, JAW-63, FTP-MW7/FTP-MW8, M-01, FTP-MW1, FTA-99-1/FTA-99-2, FTP-MW2, FTP-MW3, and G-30 northwest, southwest, south, and east of the VOC plume (Figure 5.1-5). Based on the 2019 data in these monitoring wells and historical DPT groundwater samples, the VOC plume at the FTP is delineated.

Explosives

Between 2000 and 2019, thirteen explosives were detected at the FTP (Table 5.5-2). During the most recent RI monitoring event (2019), only RDX and 4-amino-2,6-DNT exceeded their site characterization PALs and at only one location (sump well SA-99-1), as shown on Figure 5.1-4. RDX was detected at a concentration of 5.1 J µg/L at this location. RDX concentrations have been increasing at monitoring well SA-99-1 since 2002, when concentrations were nondetect. During previous sampling events, in 2000 through 2004, RDX also exceeded its PAL at FTA-99-1; however, in 2019, the RDX concentration at this location had decreased to 0.36 J µg/L.

Metals

Twelve metals have been detected in groundwater at the FTP since 2000; however, only arsenic was detected above its site characterization PAL (10 µg/L) and BTV (33.3 µg/L) during the most recent monitoring event, in 2019. Arsenic exceeded its PAL and BTV at two locations (FTA-TT-MW-02 and SA-

99-1), with the maximum arsenic concentration (56 µg/L) detected at SA-99-1, the sump well in the former training pit footprint.

Iron exceeded its PAL (14,000 µg/L) and BTV (9,736 µg/L) at five locations, and manganese exceeded its PALs (430 µg/L) and BTV (580 µg/L) at seven locations in 2010; iron and manganese were not analyzed during the 2019 RI event. However, these elevated concentrations of iron and manganese are not considered site-related and are attributed to the enhanced reducing conditions created by the treatability study (Tetra Tech, 2010). As described in Table 5.5-1, high-fructose corn syrup was injected in the subsurface to assess the potential for enhanced bioremediation of chlorinated VOCs in groundwater in 2005–2006. Analysis of iron and manganese were included in the 2005 though 2010 performance monitoring events for monitoring wells located within the treatability study boundary to help evaluate whether reducing conditions were being established. The iron and manganese exceedances were observed during these performance monitoring events.

Concentrations of some metals may be naturally elevated in the environment, and may not indicate a CERCLA-regulated release. Several metals (such as cadmium, chromium, lead, mercury, and selenium) were detected below their BTVs and PALs during the latest sampling events and are therefore considered to be naturally occurring in groundwater at the FTP.

5.5.5 Fate and Transport

This section discusses the fate and transport of site-related chemicals of interest at the FTP. This includes chemicals that were detected above both their site characterization PAL and BTV (if available) during the last sampling event that those chemicals were analyzed for. In groundwater, potential site-related chemicals of interest are VOCs (1,1,1-TCA, 1,1-DCA, 1,1-DCE, 1,2,4-trimethylbenzene, 1,2-dichloroethane, benzene, cis-1,2-DCE, methylene chloride, PCE, toluene, vinyl chloride, and o-xylene), explosives (RDX and 4-amino-2,6-DNT), and metals (arsenic). Fate and transport characteristics for these chemicals are described in Section 3.2.

The FTP area, which is part of the larger EDA, was formerly used for firefighting training operations, debris disposal, and open burning. The EDA is fenced. The FTP area is vegetated and with no remaining structures onsite. This site falls within the Spring Creek watershed (Figure 2-1); however, there are no perennial surface water features within the site boundary (Figure 5.1-1). Surface water drainage occurs through a number of intermittent drainage ditches, which ultimately discharge to Spring Creek. The groundwater at the FTP area is divided into two units, overburden and bedrock groundwater. Groundwater levels measured in the overburden aquifer ranged from approximately 4 to 14 feet btoc (Figure 5.1-3), although historically groundwater has ranged from approximately 2 to 22 feet bgs. Bedrock groundwater levels ranged from approximately 10 to 20 feet btoc in 2019.

The source of contamination at the FTP area is attributed to releases to the surface as a result of historical site operations, including chemical use, burning, and disposal. Contaminants in groundwater have been transported from the source release areas through advection and dispersion. Groundwater generally flows semiradially towards Spring Creek (to the northeast and east) and an intermittent tributary to Spring Creek (to the southeast) (Figure 5.1-3). As expected, estimated hydraulic conductivity values are slow and ranged from 0.0017 to 1.7 ft/day in overburden and between 0.00042 to 0.0076 ft/day in bedrock (Tetra Tech, 2012). Downward vertical gradients were observed in 2019. Vertical migration at the site is likely limited by the generally tight clay lithology in the overburden.

As discussed in Table 5.5-1, a groundwater treatability study was conducted in 2005–2006 at the FTP, where historically the highest VOC concentrations had been observed. DPT injection of a high-fructose corn syrup solution was completed around SA-99-1, which was installed within the footprint of the 1998 soil removal area. Following the treatability study, concentrations of PCE, TCE, and 1,1,1-TCA increased in the study area. TCE, 1,1,1-TCA, and 1,1-DCE concentrations began to decrease after an initial increase, but in some instances, results were higher than initial concentrations. PCE and TCE concentrations at SA-99-1 declined to nondetect in 2019.

Natural attenuation mechanisms that are potentially active at the FTP were evaluated. Natural attenuation includes various physical, chemical, or biological processes that under favorable conditions act without human intervention to reduce the mass, toxicity, mobility, volume, or concentration of contaminants in groundwater. A weight-of-evidence approach was used for this evaluation.

- The primary line of evidence that attenuation is occurring at a site is reduction over time in contaminant concentrations or mass, or both.
  - Two explosives (RDX and 4-amino-2,6-DNT) were detected above their site characterization PALs in one overburden sump well in 2019. RDX concentrations in this well (SA-99-1) have increased since the early 2000s; however, concentrations remain relatively low (< 10 µg/L) (Table 5.5-2). RDX was not detected in adjacent monitoring well FTA-TT-MW-05 and was detected at low levels at upgradient monitoring well JAW-63. Therefore, the extent of explosives contamination is limited.
  - Numerous VOCs associated with chlorinated solvents, fuels, and associated breakdown products have been detected at the FTP. Historically, 1,1-DCE and 1,1-DCA have exceeded their PALs with the greatest frequency. VOCs were detected above their site characterization PALs in nine overburden and transition monitoring wells during the 2019 sampling event. The maximum VOC concentration detected in 2019 was 1,1-DCA at 4,900 µg/L at FTA-TT-MW-03. Historically, the maximum concentration of 1,1-DCA was 7,500 µg/L at SA-99-1 in the 2000, although concentrations have declined at this location to 200 µg/L in 2019. This decrease in concentrations is likely a combination of the soil removal, treatability study injections, and natural attenuation. However, an increasing trend at FTA-TT-MW-03, located near the former berm to the training pit, may be indicative of a continuing source or some plume migration. Nevertheless, the lack of VOCs exceedances in the most downgradient wells (JAW-62, JAW-63, FTP-MW7/FTP-MW8, M-01, FTP-MW1, FTA-99-1/FTA-99-2, FTP-MW2, FTP-MW3, and G-30) indicate that any plume migration is limited.
  - Arsenic was also identified as a chemical of interest in groundwater. As previously discussed, total arsenic exceeded its PAL (10 µg/L) and BTV (33.3 µg/L) at only two locations in 2019 (FTA-TT-MW-02 and SA-99-1), with the maximum arsenic concentration (56 µg/L) detected at SA-99-1). Both of these wells are located in the vicinity of the former training pit and 1998 soil removal area. Arsenic concentrations in SA-99-1 have been fairly consistent since 2001.
- Reductive degradation products of TCE and PCE were detected at the FTP in 2019. Cis-1,2-DCE was detected in ten monitoring wells between <1 µg/L and 2,000 µg/L and vinyl chloride was detected in five wells between 1.3 J µg/L and 510 µg/L. Additionally, the presence of 1,1-DCE and 1,1-DCA may be due to degradation of 1,1,1-TCA (Table 5.5-2). During the 2005–2006 treatability study, groundwater samples were analyzed for ethane and ethene. Both of these dissolved gasses were detected at low levels (up to 740 µg/L), indicating that the injections likely enhanced biodegradation of the chlorinated VOCs during this time period, and full reductive dechlorination was occurring.
- No RDX degradation products (MNX, DNX, or TNX) were detected at the FTP area wells during the latest sampling event in 2019.
- Water quality parameters can be used to evaluate whether the geochemical conditions are conducive to biodegradation. During the current RI, groundwater was observed to be under anaerobic and reducing conditions in the former training pit area, near monitoring wells SA-99-1, and FTA-TT-MW-01 through FTA-TT-MW-05. DO concentrations were reported in groundwater between 0.14 and 0.55 mg/L and ORP values ranged from -5.9 to -111.7 mV in these wells. Groundwater was observed to be under aerobic and oxidizing conditions at all other monitoring

wells at the FTP area. Outside of the former main training pit area, DO concentrations in groundwater were reported between 0.59 and 6.7 mg/L, and ORP values were reported above generally +100 mV (Tables 5.1-5). pH values were relatively neutral (between 6 and 7), which is favorable for biological activity, except for one monitoring well, FTA-TT-MW-02, where the pH was 5.44.

- Under these geochemical conditions, anaerobic biodegradation of VOCs and RDX would be more favorable within the main source area (former training pit) and less favorable at the rest of the site. However, the bulk of VOC and explosives contaminant mass are present within the former training pit area. Therefore, conditions are most favorable for anerobic biodegradation in the area with the highest mass and concentrations. In regard to arsenic, concentrations will increase under reducing conditions due to reductive dissolution of iron and manganese, which the arsenic tends to sorb to.
- In areas of the site where conditions are more aerobic and oxidizing, VOC (i.e., 1,1-DCE) degradation may be less favorable. However, 1,1-DCA and TCE can degrade via aerobic cometabolism, which may explain the lack of reductive daughter products in the downgradient portion of the plume. In addition, TCE and RDX can degrade by biologic and abiotic pathways. While arsenic can be present in a form that is more mobile under oxidizing conditions, it tends to sorb or complex with clays, organic material, iron hydroxides, or manganese oxides, limiting its mobility (ERG, 2005). This may explain the lack of arsenic exceedances outside of the source area.

The physical natural attenuation processes are also likely helping to stabilize the plumes, particularly the explosives and arsenic exceedances, which have a limited extent. While the explosives in groundwater have moderate solubility and relatively low sorption potential, they should be retarded somewhat as it sorbs to the clay geology and may explain their limited extent at the FTP area. VOCs are characterized by relatively high solubilities and low sorption potential (Table 4.2-1). VOCs also have a high vapor pressure and may volatilize into soil gas at the interface with the water table.

5.5.6 Human Health Risk Assessment

An HHRA was prepared for the FTP to evaluate potential current and future health risks and hazards from exposure to chemicals in site groundwater. Soil media within the FTP is not included in the HHRA as it is not a component of this RI; the soil RI was conducted under OU-1. A brief summary of OU-1 soil COCs is provided in Section 5.5.1.3 and historical remedial activities for soil are presented in Table 5.5-1. Surface water and sediment media are not included in the HHRA because perennial surface water features are not present at the FTP. The HHRA was conducted in accordance with the final UFP-QAPP (CH2M, 2017a), with the exception of some deviations that were agreed to during meetings or correspondence with USACE and USEPA following approval of the final UFP-QAPP. The approach and methods used to conduct the HHRA are provided in Section 4.3.1. This section presents the CEM for the FTP and provides the results of the four-step evaluation process comprising the following:

- Data evaluation.
- Exposure assessment.
- Toxicity assessment.
- Risk characterization.

The results of the HHRA are used to determine whether further action is warranted for groundwater at the FTP.

5.5.6.1 Conceptual Exposure Model

A description of the FTP, its operational history, previous investigations, and remedial actions are provided in Sections 5.5.1 and 5.5.2. The site, which is no longer active, was formerly used for fire training operations, debris disposal, and open burning. The FTP is primarily grass-covered with a few roads remaining, which lead to the cleared/paved areas associated with demolished building footprints. There are no buildings within the FTP site boundary. There are no potential receptors or potentially complete exposure pathways identified under current site conditions. Although the site is open to recreational activities and hunting is permitted within the site boundary, there are no perennial surface water features within the FTP site boundary. It is assumed that the site could become active or redeveloped in the future. Although not present within the FTP site boundary, culverts are present within the extent of the VOC plume; therefore, potential groundwater exposures by future construction/utility workers are considered complete at the FTP.

Groundwater is not currently being used as a potable water source, and there are no plans to use groundwater for potable purposes in the future; however, based on applicable CERCLA policy and guidance, groundwater at the FTP is classified as Class IIB, a potential source of drinking water (USEPA, 1989). Therefore, the HHRA for the FTP evaluates potential exposures to groundwater due to its potential future use as a drinking water source. This consists of the evaluation of future residential exposures to groundwater.

The following potential future human receptors were identified in the HHRA for the FTP:

- **Future Site Workers.** Future site workers could contact groundwater based on its potential future use as a drinking water source at the FTP. If buildings are constructed onsite, future site workers could be exposed to indoor air (that may be impacted by VOCs migrating from groundwater) in future buildings.
- **Future Construction/Utility Workers.** Future construction/utility workers could contact shallow groundwater while replacing a culvert.
- **Future Hypothetical Residents.** Future hypothetical residents could contact groundwater based on its potential future use as a drinking water source at the FTP and could be exposed to indoor air (that may be impacted by VOCs migrating from groundwater) in future residences.

As discussed in Section 4.3.1, potential exposures and risks and hazards to future site workers and construction/utility workers are estimated in the HHRA only if the estimated risks or hazards for a hypothetical residential scenario exceed acceptable risk levels, and COCs are identified for a hypothetical residential scenario. The human health CEM presenting potential exposure media, exposure points, receptors (future), and exposure routes is provided in Appendix A-6, Attachment 1 (Table 1), and depicted graphically on Figure 5.5-1.

5.5.6.2 Data Evaluation

Data Used in the HHRA

The analytical data used in the HHRA consisted of groundwater samples collected at the FTP in March 2019. Groundwater samples were analyzed for explosives, metals, PAHs, SVOCs, and VOCs. It should be noted that the evaluation of PFOS, PFBS, and PFOA at the FTP has not been completed, and therefore PFAS is not a component of this OU-10 RI. Twenty-six groundwater samples were used to evaluate potential exposures for both a potable use scenario and the VI pathway. The groundwater samples were not collected at multilevel wells; therefore, a separate data grouping (based on shallow groundwater only) was not used to evaluate the VI pathway. A separate groundwater data grouping was used to evaluate a construction/utility worker scenario, assuming construction/utility workers could be exposed to groundwater encountered at depths up to 10 feet bgs. Fifteen groundwater samples were used to evaluate potential exposures in a trench for a construction/utility worker.

A summary of the number of chemicals analyzed and detected in groundwater is presented below:

Chemical Group	Number of Chemicals Analyzed	Number of Chemicals Detected
Groundwater		
Explosives	17	4
Metals	8	3
PAHs	1	1
SVOCs	5	1
VOCs	61	30

A description of the data groupings and samples included in the HHRA are provided in Tables 5.5-3 and 5.5-4, respectively. The analytical dataset used in the HHRA is included as Appendix A-6, Attachment 2.

Screening Results for Site-related Chemicals of Potential Concern and Naturally Occurring Chemicals

The approach and SLs used to select the COPCs (site-related COPCs or naturally occurring chemicals) are described in Section 4.3.1. The results of the COPC screening process are provided in Appendix A-6, Attachment 1 (Tables 2.1 through 2.3). As summarized below, three explosives, two metals, one PAH, and 22 VOCs were identified as COPCs (site-related COPCs or naturally occurring chemicals) in groundwater for a potable use scenario. Thirteen VOCs were identified as COPCs in groundwater for vapor intrusion. Three explosives, two metals, one PAH, and 22 VOCs were identified as COPCs in groundwater for a construction/utility worker scenario. The COPCs (site-related COPCs or naturally occurring chemicals) are addressed further in the HHRA, and potential exposures and risks and hazards were estimated for each COPC (site-related COPC). No naturally occurring chemicals were identified as COPCs.

Summary of COPCs for the FTP—Site-Related*

Receptor	COPC	Frequency of Detections	Minimum Detection (µg/L)	Maximum Detection (µg/L)
Groundwater Used for Tap Water				
Future Site Worker and Future Hypothetical Resident	2-Amino-4,6-dinitrotoluene	1 / 10	1.2	1.2
	4-Amino-2,6-dinitrotoluene	1 / 10	4.4	4.4
	RDX	4 / 10	0.36	5.1
	Arsenic	4 / 13	17	56
	Barium	13 / 13	42	2000
	Naphthalene	2 / 24	3.7	10
	1,1,1-Trichloroethane	11 / 24	0.24	2000
	1,1,2-Trichloroethane	4 / 24	0.4	2.5
	1,1-Dichloroethane	14 / 24	0.58	4900
	1,1-Dichloroethene	10 / 24	1.4	270
	1,2,4-Trimethylbenzene	5 / 24	0.33	110
	1,2-Dichloroethane	7 / 24	0.82	81

Summary of COPCs for the FTP—Site-Related*

Receptor	COPC	Frequency of Detections	Minimum Detection (µg/L)	Maximum Detection (µg/L)
	1,3,5-Trimethylbenzene	4 / 24	4.7	34
	Acetone	2 / 24	200	6700
	Benzene	7 / 24	0.87	88
	Chloroethane	6 / 24	2.5	1100
	Chloroform	1 / 24	0.35	0.35
	cis-1,2-Dichloroethene	11 / 24	0.45	2000
	Ethylbenzene	6 / 24	0.31	130
	Methyl ethyl ketone	2 / 24	44	5100
	Methyl isobutyl ketone	2 / 24	110	1700
	Methylene chloride	3 / 24	7.6	160
	Tetrachloroethene	7 / 24	0.38	59
	Toluene	5 / 24	0.18	3500
	Trichloroethene	7 / 24	0.22	82
	Vinyl chloride	5 / 24	0.24	510
	Xylene, m,p-	5 / 24	0.19	570
	Xylene, o-	4 / 24	14	210
Groundwater to Indoor Air via Vapor Intrusion				
Future Site Worker and Future Hypothetical Resident	1,1,1-Trichloroethane	11 / 24	0.24	2000
	1,1,2-Trichloroethane	4 / 24	0.4	2.5
	1,1-Dichloroethane	14 / 24	0.58	4900

	Xylene, m,p-	5 / 14	0.19	570
	Xylene, o-	4 / 14	14	210

* No COPCs at FTP are naturally occurring.

5.5.6.3 Exposure Assessment

The FTP is currently inactive, and former buildings have been demolished. The site is open to recreational activities, and hunting is permitted within the site boundary; however, there are no perennial surface water bodies within the FTP site boundary. Therefore, there are no potentially complete exposure pathways identified under current site conditions.

As previously discussed, groundwater is not currently being used as a potable water source; however, the HHRA for the FTP evaluated potential exposures to groundwater due to its potential future use as a drinking water source. This consists of the evaluation of future residential exposures to groundwater. Therefore, ingestion and dermal contact exposures to COPCs in groundwater were estimated for future site workers and hypothetical residents.

Additionally, inhalation exposures to site groundwater were evaluated for hypothetical residents assuming VOCs could be present in household air as a result of showering, bathing, and other household activities. The vapor intrusion pathway is also considered potentially complete for groundwater if future industrial buildings or residences are constructed at the FTP; therefore, potential inhalation exposures to indoor air were evaluated for site workers and hypothetical residents.

Culverts are located within the VOC plume associated with the FTP; therefore, potential ingestion, dermal contact, and inhalation exposures to shallow groundwater in a trench were evaluated for future construction/utility workers. The potential exposure pathways quantified in the HHRA are included in Appendix A-6, Attachment 1 (Table 1), and on Figure 5.5-1. The following receptor scenarios were quantified in the HHRA for the FTP:

- Future Site Worker
  - Groundwater (tap water) COPCs—ingestion and dermal contact
  - Groundwater (vapor intrusion) COPCs—inhalation of volatiles in indoor air
- Future Construction/Utility Worker
  - Shallow groundwater (trench, 0 to 10 feet bgs) COPCs—incidental ingestion, dermal contact and inhalation of volatiles
- Future hypothetical residents (adult and child)
  - Groundwater (tap water) COPCs—ingestion, dermal contact, and inhalation of volatiles in household air
  - Groundwater (vapor intrusion) COPCs—inhalation of volatiles in indoor air

Risks and hazards for site workers and construction/utility workers were quantified in the HHRA because the estimated risks or hazards for a hypothetical residential scenario exceeded acceptable risk or hazard levels and COCs were identified for a residential scenario.

In accordance with USEPA guidance *Determining Groundwater Exposure Point Concentrations, Supplemental Guidance* (USEPA, 2014b), groundwater EPCs are typically calculated based on the data collected in the core of a plume. One RDX and one VOC plume are present at the FTP (Figures 5.1-4 and 5.1-5, respectively). Four groundwater samples are available in the HHRA dataset for the RDX plume, and 14 groundwater samples are available for the VOC plume. Four shallow groundwater samples are available for the RDX plume, and nine shallow groundwater samples are available for the VOC plume.

Fourteen monitoring wells are located within the core of the VOC plume: FTA-TT-MW-01, FTA-TT-MW-02, FTA-TT-MW-03, FTA-TT-MW-04, FTA-TT-MW-05, FTP-MW4, FTP-MW5, FTP-MW6, JAW-58, JAW-59, JAW-60, JAW-61, JAW-80, and SA-99-1. Five monitoring wells are located within the core of the RDX plume: FTA-TT-MW-01, FTA-TT-MW-02, FTA-TT-MW-03, FTA-TT-MW-04, and SA-99-1. For a potable use scenario and trench/culvert scenario, the monitoring wells within the RDX plume were used to estimate the EPCs for the COPCs that were explosives, and the monitoring wells within the VOC plume were used to estimate the EPCs for the COPCs that were identified as VOCs. For the VI pathway, the sitewide dataset was used to estimate the EPCs.

For COPCs with at least four detected concentrations and eight samples available in the VOC and RDX groundwater plume datasets, UCLs were calculated using USEPA's ProUCL software (USEPA, 2016), and the UCLs were selected as the EPCs. Thirteen COPCs had fewer than four detected concentrations and/or fewer than eight samples; therefore, a reliable UCL could not be estimated, and the maximum detected concentrations from the plumes were selected as the EPCs for these COPCs. For the VI pathway, the maximum detected concentration of each COPC was used as the EPC. The groundwater EPCs used to estimate the chemical intakes for each receptor scenario are provided in Appendix A-6, Attachment 1 (Tables 3.1 through 3.3). The ProUCL output for the COPCs is provided in Appendix A-6, Attachment 3.

The exposure factors used in the intake calculations for future receptor scenarios are included in Appendix A-6, Attachment 1 (Tables 4.1 through 4.5). The primary references for the exposure factor values are the standard default exposure factors presented in the HHEM (USEPA, 2014a).

Three COPCs (methylene chloride, TCE, and vinyl chloride) were identified as acting with an MMOA in site groundwater. The ADAFs and exposure assumptions used to calculate adjusted intakes and exposure concentrations for these COPCs are provided in Appendix A-6, Attachment 1 (Table 4 Supplement).

5.5.6.4 Toxicity Assessment

The oral toxicity values (CSFs and RfDs) and inhalation toxicity values (IURs and RfCs) used in the HHRA were obtained from the USEPA standard hierarchy of toxicity value sources (USEPA, 2003b), as provided in Section 4.3.1. Noncancer toxicity values for the COPCs identified at the FTP are provided in Appendix A-6, Attachment 1 (Tables 5.1 and 5.2). Cancer toxicity values for the COPCs are provided in Appendix A-6, Attachment 1 (Tables 6.1 and 6.2).

5.5.6.5 Risk Characterization

The risk characterization for the FTP was completed using a four-step process, as discussed in Section 4.3.1. The results of each step are discussed below.

Step 1: Total Combined Risks and Hazards from Site-related COPCs and Naturally Occurring Chemicals

Step 1 consists of calculating receptor-specific ELCRs and HIs that include contributions from both site-related COPCs and naturally occurring chemicals. No naturally occurring chemicals were identified as COPCs. The estimated risks and hazards for a hypothetical residential scenario are summarized below in Table 5.5-5 in Step 3.

Step 2: Risk Characterization of Naturally Occurring Chemicals

Step 2 consists of calculation of receptor-specific ELCRs and HIs for naturally occurring chemicals (if any). However, no naturally occurring chemicals were identified in site groundwater at the FTP, and therefore this step was not performed.

Step 3: Risk Characterization of Site-related COPCs

Step 3 consists of calculating receptor-specific ELCRs and HIs associated with site-related COPCs. All COPCs evaluated in Step 1 were identified as site-related COPCs for groundwater at the FTP. The estimated risks and hazards for COPCs in groundwater for a future site worker, construction/utility worker, and hypothetical resident are provided in Table 5.5-5.

Table 5.5-5. Summary of Risk and Hazard Estimates for Site-Related COPCs—IAAP-039G: Fire Training Pit Groundwater

Iowa Army Ammunition Plant, Middletown, Iowa

Receptor [a]	ELCR/HI Tables (RME) in Appendix A-6, Attachment 1	Exposure Medium	COPC	Fire Training Pit		
				EPC [b]	ELCR	HI
Site Worker	7.4 and 9.4	Groundwater (Tap water)	2-Amino-4,6-dinitrotoluene	1.2E+00	NA	0.1
			4-Amino-2,6-dinitrotoluene	4.4E+00	NA	0.4
			RDX	5.1E+00	1E-06	0.01
			Arsenic	5.6E+01	3E-04	2
			Barium	2.0E+03	NA	0.09
			1,1,1-Trichloroethane	1.6E+03	NA	0.007

			Total ELCR (Groundwater—Indoor Air): [c]		**1E-03**	**NA**
		Total ELCR (Groundwater—Tap Water and Indoor Air): [c]			**1E-02**	**NA**

Notes:

µg/L = microgram per liter
EPC = exposure point concentration
µg/m³ = microgram per cubic meter
HI = hazard index
COPC = chemical of potential concern
NA = not applicable
ELCR = excess lifetime cancer risk
RME = reasonable maximum exposure

[a] ELCRs were estimated for the adult/child aggregate receptor based on lifetime exposure and noncarcinogenic HIs were estimated separately for adult and child residents.

[b] EPC Units: groundwater (tap water) and shallow groundwater (trench) - µg/L; groundwater (indoor air—vapor intrusion) and shallow groundwater (trench air) - µg/m³

[c] The COPCs contributing to the ELCR and HI exceedances are summarized in Tables 10.1 through 10.5 in Attachment 1 of Appendix A-6.

Step 4: Final COC Determination

For groundwater (potable use) and indoor air (VI of groundwater) by future hypothetical residents, the target organ–specific HIs exceeded USEPA's threshold of 1 and the cumulative ELCR exceeded USEPA's acceptable risk range (1×10^{-6} to 1×10^{-4}) due to the COPCs indicated below:

Future Hypothetical Resident		
Groundwater Exposure Pathway	**Chemicals Causing Receptor Target Organ HI > 1**	**Chemicals Causing Receptor ELCR > 1 × 10^{-4}**
Potable use	2-Amino-4,6-dinitrotoluene, 4-amino-2,6-dinitrotoluene, arsenic, barium, 1,1,1-trichloroethane, 1,1,2-trichloroethane, 1,1-dichloroethane, 1,1-dichloroethene, 1,2,4-trimethylbenzene, 1,2-dichloroethane, acetone, benzene, cis-1,2-dichloroethene, methyl ethyl ketone, methylene chloride, PCE, toluene, TCE, vinyl chloride, m,p-xylene, and o-xylene	RDX, arsenic, 1,1,2-trichloroethane, 1,1-dichloroethane, 1,2-dichloroethane, benzene, ethylbenzene, methylene chloride, naphthalene, PCE, TCE, and vinyl chloride
Indoor air (VI)	1,1,1-Trichloroethane, 1,1,2-trichloroethane, 1,1-dichloroethene, 1,2,4-trimethylbenzene, 1,2-dichloroethane, benzene, cis-1,2-dichloroethene, PCE, TCE, vinyl chloride, m,p-xylene, and o-xylene	1,1-Dichloroethane, 1,2-dichloroethane, benzene, ethylbenzene, PCE, TCE, and vinyl chloride

The federal MCLs for the COPCs (potable use) are presented below:

Chemical	**Maximum Detected Concentration (µg/L)**	**MCL (µg/L)**	**Exceeds MCL?**	**Groundwater COC for Potable Use Scenario?**
1,1,1-Trichloroethane	2,000	200	Yes	Yes
1,1,2-Trichloroethane	2.5	5	No	No
1,1-Dichloroethane	4,900	NA	NA	Yes
1,1-Dichloroethene	270	7	Yes	Yes
1,2,4-Trimethylbenzene	110	NA	NA	Yes
1,2-Dichloroethane	81	5	Yes	Yes
2-Amino-4,6-dinitrotoluene	1.2	NA	NA	Yes
4-Amino-2,6-dinitrotoluene	4.4	NA	NA	Yes
Acetone	6,700	NA	NA	Yes
Arsenic	56	10	Yes	Yes
Barium	2,000	2,000	No	No
Benzene	88	5	Yes	Yes
cis-1,2-Dichloroethene	2,000	70	Yes	Yes
Ethylbenzene	130	700	No	No
Methyl ethyl ketone	5,100	NA	NA	Yes
Methyl isobutyl ketone	1,700	NA	NA	Yes
Methylene chloride	160	5	Yes	Yes
Naphthalene	10	NA	NA	Yes
RDX	5.1	NA	NA	Yes
Tetrachloroethene	59	5	Yes	Yes

Chemical	Maximum Detected Concentration (µg/L)	MCL (µg/L)	Exceeds MCL?	Groundwater COC for Potable Use Scenario?
Toluene	3,500	1,000	Yes	Yes
Trichloroethene	82	5	Yes	Yes
Vinyl chloride	510	2	Yes	Yes
Xylene, m,p-	570	NA	NA	Yes
Xylene, o-	210	NA	NA	Yes

Notes:

µg/L = microgram per liter

COC = chemical of concern

MCL = Maximum Contaminant Level

NA = not applicable

These chemicals were identified as COCs in groundwater for future hypothetical residents with the exception of one metal (barium) and two VOCs (1,1,2-trichloroethane and ethylbenzene), which were detected at concentrations less than their respective MCLs. These chemicals were not identified as COCs in groundwater at the FTP for potable use. However, 1,1,2-trichloroethane and ethylbenzene were identified as COCs for indoor air (i.e., VI in groundwater), as shown in Appendix A-6, Attachment 1, Tables 10.3–10.5.

Because COCs were identified for future hypothetical residents, potential exposures and risks and hazards were also estimated for future site workers and construction/utility workers (summarized in Table 5.5-5).

For groundwater (potable use) and indoor air (VI of groundwater) for future site workers, the target organ–specific HIs exceeded USEPA's threshold of 1, and the cumulative ELCR exceeded USEPA's acceptable risk range (1×10^{-6} to 1×10^{-4}) due to the COPCs indicated below:

Future Site Worker		
Groundwater Exposure Pathway	**Chemicals Causing Receptor Target Organ HI > 1**	**Chemicals Causing Receptor ELCR > 1×10^{-4}**
Potable use	4-Amino-2,6-dinitrotoluene, arsenic, 1,1-dichloroethane, cis-1,2-dichloroethene, methylene chloride, TCE, and vinyl chloride	Arsenic, 1,1-dichloroethane, 1,2-dichloroethane, benzene, naphthalene, TCE, and vinyl chloride
Indoor air (VI)	1,1-Dichloroethene, cis-1,2- dichloroethene, TCE, and vinyl chloride	1,1-Dichloroethane, 1,2-dichloroethane, benzene, ethylbenzene, TCE, and vinyl chloride

For contact with shallow groundwater by future construction/utility workers, the target organ–specific HIs exceeded USEPA's threshold of 1 due to the COPCs indicated below; the cumulative ELCR did not exceed USEPA's acceptable risk range (1×10^{-6} to 1×10^{-4}):

Future Construction/Utility Worker		
Groundwater Exposure Pathway	**Chemicals Causing Receptor Target Organ HI > 1**	**Chemicals Causing Receptor ELCR > 1×10^{-4}**
Shallow Groundwater	TCE	

Trench air	Naphthalene, benzene, methyl ethyl ketone, methyl isobutyl ketone, methylene chloride, PCE, toluene, TCE, vinyl chloride, m,p-xylene, and o-xylene	None

In summary, the following COCs were identified for groundwater, as presented in tables in Appendix A-6, Attachment 1:

Chemical	**Site Workers (Table 10.1)**	**Construction/Utility Workers (Table 10.2)**	**Hypothetical Residents (Tables 10.3–10.5)**

5.5.6.6 Uncertainty Analysis

The assumptions used in the HHRAs have inherent uncertainty. The general uncertainties associated with the HHRAs for the sites in this RI report are provided in Section 4.3.1. This section provides additional site-specific uncertainties associated with the HHRA for the FTP that are not included in Section 4.3.1.

The maximum RL of detected chemicals not identified as COPCs in the RAGS Table 2 Series (Appendix A-2, Attachment 1) was compared to their respective RSL. However, chemicals whose RL exceeds the RSL were not identified as COPC. For the FTP, RLs exceeded RSLs for one metal (selenium) and two VOCs (1,2-dichlorobenzene and trans-1,2-dichloroethene). Although the RLs for these detected chemicals are greater than the RSLs, based on the frequency of exceedance, probable chemical interference from detected VOCs and comparison to historically detected chemicals in groundwater at IAAAP, further consideration of these detected chemicals does not appear warranted in the FTP HHRA.

Hazard estimates for 2-amino-4,6-dinitrotoluene, 4-amino-2,6-dinitrotoluene, and 1,2-dichloroethane could be over- or underestimated because screening RfDs were used in the risk calculations. For example, as stated in the PPRTV document for 4-amino-2,6-dinitrotoluene (USEPA, 2020c),

> It is inappropriate to derive a subchronic or chronic provisional RfD for 4-amino-2,6-dinitrotoluene. However, information is available which, although insufficient to support derivation of a provisional toxicity value, under current guidelines, may be of limited use to risk assessors.… Users of screening toxicity values in an appendix to a PPRTV assessment should understand that there is considerably more uncertainty associated with the derivation of a supplemental screening toxicity value than for a value presented in the body of the assessment.

Chemicals that were 100 percent not detected in an exposure medium were not included in the COPC identification process; however, they were evaluated in a separate screening to determine whether elevated nondetected results were present in site media. The detailed analysis of the nondetected chemicals at the FTP is provided in Appendix A-6, Attachment 4. In summary, four explosives (2,4-dinitrotoluene, 2,6-dinitrotoluene, 2-nitrotoluene, and nitrobenzene), two metals (chromium and mercury), three SVOCs, and 21 VOCs had RLs or DLs exceeding SLs at the FTP. Although the maximum DLs and/or RLs for these nondetect chemicals are greater than the SLs, based on the frequency of exceedance, comparison to historically detected chemicals in groundwater at IAAAP, and acceptably low DLs and RLs for most samples, further consideration of nondetect chemicals does not appear warranted in the FTP HHRA.

5.5.6.7 Summary of HHRA

An HHRA was prepared for the FTP to evaluate potential current and future health risks from exposure to chemicals in site groundwater. The FTP is currently inactive, and former buildings have been demolished. The site is open to recreational activities, and hunting is permitted within the site boundary; however, there are no perennial surface water bodies within the FTP site boundary. Therefore, there are no potentially complete exposure pathways identified under current site conditions.

The following potential future human receptors were identified in the HHRA for the FTP:

- **Future Site Workers.** Future site workers could contact groundwater based on potential future use as a drinking water source at the FTP. If buildings are constructed onsite, future site workers could be exposed to indoor air (that may be impacted by VOCs migrating from groundwater) in future buildings.
- **Future Construction/Utility Workers.** Future construction/utility workers could contact shallow groundwater while replacing a culvert located within the VOC plume.
- **Future Hypothetical Residents.** Future hypothetical residents could contact groundwater based on potential future use as a drinking water source at the FTP and could be exposed to indoor air (that may be impacted by VOCs migrating from groundwater) in future buildings.

Potential exposures and risks and hazards to future site workers and construction/utility workers were estimated in the HHRA since estimated risks and hazards for a hypothetical residential scenario exceeded acceptable risk and hazard levels and COCs were identified for a residential scenario.

The COPCs (site-related COPCs or naturally occurring chemicals) identified in site groundwater are as follows:

- Groundwater (potable use):
  - Naturally occurring: none.
  - Site-related: 2-amino-4,6-dinitrotoluene, 4-amino-2,6-dinitrotoluene, RDX, arsenic, barium, naphthalene, 1,1,1-trichloroethane, 1,1,2-trichloroethane, 1,1-dichloroethane, 1,1-dichloroethene, 1,2,4-trimethylbenzene, 1,2-dichloroethane, 1,3,5-trimethylbenzene, acetone, benzene, chloroform, cis-1,2-dichloroethene, ethylbenzene, methyl ethyl ketone, methyl isobutyl ketone, methylene chloride, tetrachloroethene, toluene, trichloroethene, vinyl chloride, m,p-xylene, and o-xylene.
- Groundwater (vapor intrusion):
  - Naturally occurring: none.
  - Site-related: 1,1,1-trichloroethane, 1,1,2-trichloroethane, 1,1-dichloroethane, 1,1-dichloroethene, 1,2,4-trimethylbenzene, 1,2-dichloroethane, benzene, cis-1,2- dichloroethane, ethylbenzene, tetrachloroethene, trichloroethene, vinyl chloride, m,p-xylene, and o-xylene.
- Groundwater (trench scenario):
  - Naturally occurring: none.
  - Site-related: 2-amino-4,6-dinitrotoluene, 4-amino-2,6-dinitrotoluene, RDX, arsenic, barium, naphthalene, 1,1,1-trichloroethane, 1,1,2-trichloroethane, 1,1-dichloroethane, 1,1-dichloroethene, 1,2,4-trimethylbenzene, 1,2-dichloroethane, 1,3,5-trimethylbenzene, acetone, benzene, chloroform, cis-1,2-dichloroethene, ethylbenzene, methyl ethyl ketone, methyl isobutyl ketone, methylene chloride, tetrachloroethene, toluene, trichloroethene, vinyl chloride, m,p-xylene, and o-xylene.

The risk characterization for the FTP was completed using a four-step process, as discussed in Section 4.3.1. Step 1 presents the total combined risks and hazards from site-related COPCs and naturally occurring chemicals. Step 2 presents the risks and hazards from naturally occurring chemicals; however, no naturally occurring chemicals were identified in groundwater at the FTP. Step 3 presents the risks and hazards from site-related COPCs, as summarized in Table 5.5-5.

Unacceptable groundwater risks and hazards were identified in Step 3 for hypothetical residents, and in Step 4, explosives, VOCs, and one metal (arsenic) were identified as COCs for future hypothetical residents. Therefore, groundwater risks and hazards were also estimated for future site workers and construction/utility workers. For future site workers, explosives and VOCs were identified as COCs in groundwater; for future construction/utility workers, VOCs were identified as COCs in shallow groundwater.

In summary, the following COCs were identified for groundwater:

Future Site Worker	Future Construction / Utility Worker	Future Hypothetical Resident
1,1-Dichloroethane	Benzene	1,1,1-Trichloroethane
1,1-Dichloroethene	Naphthalene	1,1,2-Trichloroethane
1,2-Dichloroethane	Methyl ethyl ketone	1,1-Dichloroethane
4-Amino-2,6-dinitrotoluene	Methyl isobutyl ketone	1,1-Dichloroethene

Future Site Worker	Future Construction / Utility Worker	Future Hypothetical Resident
Arsenic	Methylene chloride	1,2,4-Trimethylbenzene
Benzene	Tetrachloroethene	1,2-Dichloroethane
cis-1,2- Dichloroethane	Toluene	2-Amino-4,6-dinitrotoluene
Ethylbenzene	TCE	4-Amino-2,6-dinitrotoluene
Methylene chloride	Vinyl chloride	Acetone
Naphthalene	Xylene, m,p-	Arsenic
TCE	Xylene, o-	Benzene
Vinyl chloride		cis-1,2-Dichloroethene
		Ethylbenzene
		Methyl ethyl ketone
		Methyl isobutyl ketone
		Methylene chloride
		Naphthalene
		RDX
		Tetrachloroethene
		Toluene
		Trichloroethene
		Vinyl chloride
		Xylene, m,p-
		Xylene, o-

5.5.7 Ecological Risk Assessment

The ERA for groundwater at the FTP is presented herein, beginning with Step 1 of the ERA process (to determine whether there are complete exposure pathways). Soil at the FTP is already addressed under the remedy for OU-1. There are no perennial surface water features within the FTP boundary; however, Spring Creek is present east of the FTP. A summary of the ERA conclusions for Spring Creek are provided in the ERA for the WBPA (Section 5.2.7).

Groundwater is present onsite, but ecological receptors are not exposed directly to groundwater; nevertheless, groundwater is a transport medium, and contaminated groundwater has potential to migrate to and discharge to surface water bodies. There is a lack of perennial surface water bodies on the FTP. Therefore, the groundwater-to-surface-water exposure pathway is incomplete. There are no complete exposure pathways for ecological receptors on the site. Therefore, there are no adverse effects identified and no additional actions are required from an ecological perspective.

5.5.8 Conclusions and Recommendations

An RI was conducted for the FTP to refine the nature and extent of contamination in groundwater from historical activities and assess for potentially unacceptable risk to human health and adverse effects to the environment. Analytical data available for groundwater at FTP includes VOCs, SVOCs, PAHs, explosives, metals, PCBs, radionuclides, and pesticides. Of these, VOCs, explosives, and metals were identified as site-related chemicals of interest based on historical site operations and a comparison of concentration data to site characterization PALs and BTVs (See Section 4.1). The FTP was identified as an AOPI during a Preliminary Assessment for PFAS at IAAAP (Arcadis, 2020). The PFAS AOPIs are currently under a site inspection, and therefore PFAS is not a component of this OU-10 RI.

In groundwater, 13 VOCs (1,1,1-TCA, 1,1-DCA, 1,1-DCE, 1,2,4-trimethylbenzene, 1,2-dichloroethane, benzene, cis-1,2-DCE, methylene chloride, PCE, TCE, toluene, vinyl chloride, and o-xylene), two explosives, and one metal (arsenic) were detected above their site characterization PALs or BTVs (if available) during the most recent sampling event in 2019. VOC groundwater contamination is present as one large plume, with the majority of VOC contamination within the footprint of the former main training pit and 1998 soil removal area. The VOC plume is considered to be laterally and vertically delineated. On the contrary, the explosives plume is isolated to the sump well (SA-99-1), located within the 1998 removal area. Arsenic groundwater contamination was observed within the vicinity of the former training pit and 1998 soil removal area, and arsenic concentrations have been fairly consistent in this area since 2001. The slow groundwater flow velocity and natural attenuation processes are likely helping to limit the extent of plume migration. As such, no contaminant exceedances have been observed in the most downgradient monitoring wells in this area.

The soil removals that were completed in 1998 and 2003 are assumed to have removed the bulk of VOC contamination that could be a source to groundwater. Confirmation samples were below the excavation criteria.

An HHRA and an ERA were conducted to quantify potential risks and hazards to human health and the environment from exposure to contaminants at the FTP. The following conclusions were made based on the risk assessments:

- The HHRA identified potentially unacceptable risks and hazards for the following receptors from exposure to groundwater at the FTP:

Site Receptor	Chemicals (COCs)
Site Workers	1,1-Dichloroethane, 1,1-dichloroethene, 1,2-dichloroethane, 4-amino-2,6-dinitrotoluene, arsenic, benzene, ethylbenzene, methylene chloride, naphthalene, TCE, and vinyl chloride
Construction/Utility Workers	Benzene, naphthalene, methyl ethyl ketone, methyl isobutyl ketone, methylene chloride, tetrachloroethene, toluene, TCE, vinyl chloride, m,p-xylene, and o-xylene
Hypothetical Residents	1,1,1-Trichloroethane, 1,1,2-trichloroethane, 1,1-dichloroethane, 1,1-dichloroethene, 1,2,4-trimethylbenzene, 1,2-dichloroethane, 2-amino-4,6-dinitrotoluene, 4-amino-2,6-dinitrotoluene, acetone, arsenic, benzene, cis-1,2-DCE, ethylbenzene, methyl ethyl ketone, methyl isobutyl ketone, methylene chloride, naphthalene, RDX, PCE, toluene, TCE, vinyl chloride, m,p-xylene, and o-xylene

- The ERA concluded that there are no adverse effects to ecological receptors identified and no additional actions are required from an ecological perspective.

Based on the results of the RI and risk assessments, additional action is warranted to mitigate potentially unacceptable risks to future receptors from site-related COCs in groundwater (VOCs, explosives, and arsenic). It is recommended that an FS should be completed under OU-10 to evaluate remedial alternatives to address the unacceptable risks in groundwater at the FTP (IAAP-039G). When developing remedial alternatives, the FS should consider the reasonably foreseeable future land use for this area.

OU-10 Conclusions and Recommendations Summary

An RI was conducted for the environmental sites within the EDA to refine the nature and extent of contamination in applicable media from historical activities, assess for potentially unacceptable risk to human health and adverse effects to the environment, and recommend a path forward.

6.1 RI Conclusions

6.1.1 EBPs (IAAP-012G)

Potential sources of contamination at the EBPs include historical activities associated with open burning of explosives-contaminated metals, propellants, explosives, and pyrotechnic-contaminated materials. Available documentation does not indicate that petroleum fuels or other liquid accelerants were used for open burning operations. Explosive powder that was used to initiate the flashing was spread on top of materials placed on the burn pads. Live ordnance was not demilitarized (Tetra Tech, 2006). Scrap metal was recovered for offsite recycling, and ash and other debris were disposed of offsite. Operations at the EBPs ceased once the EWI was constructed in 1982.

Based on historical site operations and a comparison of the most current concentration data to site characterization project action limits (PALs) and background threshold values (BTVs), only RDX was identified as a potential site-related chemical of interest in groundwater. RDX groundwater contamination is present as one large plume, which exists primarily within the overburden aquifer. It was detected above its site characterization PAL in only four overburden and shallow bedrock monitoring wells during the latest sampling events (EBP-MW3, EBP-MW4, EBP-MW5, and EDA-2). Although RDX concentrations in three out of the four wells have decreased since late 2007, increasing trends at monitoring wells EBP-MW4 and EDA-3, located at the leading edge of the plume, may be indicative of some plume migration. However, the overburden aquifer is absent in the western portion of the site, where it pinches out and bedrock outcrops to the surface. Along with the slow groundwater flow velocity, this may be limiting the extent of plume migration. As such, no RDX exceedances have been observed in the most downgradient monitoring wells at the site. The RDX plume is considered to be laterally and vertically delineated.

The soil removal that was completed in 1999 is assumed to have removed the bulk of RDX contamination that could be a source to groundwater. Although initial confirmation sampling showed RDX concentrations above the OU-1 leachability-based RG (1.3 mg/kg) at Pads 1E, 2E, 4E, 5E, 6E, and 8E, an additional 1 to 2 feet of soil was excavated in these areas following the confirmation sampling. Because a second round of confirmation sampling was not conducted, it is unknown whether RDX concentrations in soil still exceeded the leachability goal at the EBPs.

The HHRA did not identify any unacceptable risks or hazards for future residential receptors exposed to site-related chemicals in groundwater at the EBPs. The ERA concluded that no adverse effects to ecological receptors exist at the EBPs, given the lack of complete exposure pathways for ecological receptors.

6.1.2 WBPA (IAAP-032G)

Potential sources of contamination at WBPA include historical activities associated with open burning demilitarization activities and burning and disposal of dunnage. Open burning was performed on a variety of munitions debris and related materials, including explosives-contaminated metals parts and inert and explosives-contaminated packaging. Recoverable metal was segregated for offsite recycling and reuse subsequent to burning. Land disposal was performed at onsite landfills for other wastes from burning operations, including ash, paper, wood, and metal cans. Burning and disposal operations at the WBPA ceased after the EWI was constructed in 1982.

Based on historical site operations and a comparison of the most current concentration data to site characterization PALs and BTVs, three explosives (RDX, 2,6-DNT, and 1,3-dinitrobenzene), four VOCs (1,1,2-trichlorotrifluoroethane [Freon 113], 1,1-dichloroethane, 1,1-DCE, and TCE) and one metal (arsenic) were identified as potential site-related chemicals of interest in groundwater. RDX is the most extensive chemical, and the other explosives are present within the RDX plume extents. RDX is present primarily as one large plume, which exists primarily within the overburden and shallow bedrock aquifers. The soil removals are assumed to have removed the bulk of RDX contamination that could be a source to groundwater. However, confirmation samples collected in 2000 from the four excavation areas (WBP Landfill, Pad 2-W, Burn Cage Ash Landfill, and Pad 1-W) indicated that RDX was still present above OU-1 leachability RGs (ECC, 2001), which could be a continuing source at the WBPA. VOCs are present in three plumes at the WBPA, two in the northern portion of the WBPA and one in the eastern portion of the WBPA. Of note is a large VOC plume that extends into the southeastern corner of the WBPA; however, this plume is associated with the FTP site (IAAP-039). Arsenic exceeded its PAL and BTV at only one well in 2019.

A groundwater treatability study was conducted from 2005 through 2009 in the northwest portion of the RDX plume, near WBP-TTMW-05B, and in the southeast portion of the RDX plume, near WBP-99-3, where historically the highest RDX and Freon 113 concentrations had been observed. Stable and decreasing RDX concentrations are north and east of the RDX plume; however, some increasing trends may be indicative of some plume migration or rebound following the treatability study injections. However, the slow groundwater flow velocity should be limiting the extent of plume migration. The RDX plume is considered to be laterally and vertically delineated for this RI. In surface water, only dissolved aluminum was detected above its site characterization PAL and BTV in 2019, downstream of the EDA. Dissolved aluminum was not detected upstream of the EDA in 2019. No site-related chemicals of interest were identified for sediment.

The HHRA identified potentially unacceptable risks for future hypothetical residential receptors exposed to site-related chemicals in groundwater at the WBPA, including VOCs, explosives, and arsenic. The HHRA also identified potentially unacceptable risks associated with exposure to Freon 113, 1,3-dinitrobenzene, 2,6-dinitrotoluene, arsenic, chloroform, dichlorodifluoromethane, RDX, and TCE for current and/or future site workers and to TCE for construction/utility workers. The HHRA concluded that there are no unacceptable risks or hazards for hypothetical residents from exposure to surface water or sediment at the WBPA.

The ERA concluded that no adverse effects to ecological receptors exist at the WBPA. Surface water and sediment data were evaluated in the 2022 Watershed ERA (Appendix I) for the Spring Creek watershed. From the SLERA, copper and silver in sediment were identified as COPECs; these COPECs were carried forward into the BERA for the 2022 Watershed ERA. No chemicals were identified as COPECs in surface water. Following the weight-of-evidence evaluation, no COPECs were identified for Spring Creek. The recommendation of NFA for the Spring Creek watershed based on the results of the Watershed ERA (Appendix I) means that no ecological impacts are expected at the WBPA.

6.1.3 NBPs (IAAP-036G)

Potential sources of contamination at NBPs include historical activities associated with open burning activities, including of lead azide and gunpowder. Incomplete combustion of explosives compounds and metals from ash released to soil may have leached into groundwater.

Based on historical site operations and a comparison of the most current concentration data to site characterization PALs and BTVs, no contaminants were detected as potential site-related chemicals of interest in groundwater. Historically, explosives, VOCs, and metals were identified as chemicals of interest in groundwater at the NBPs; however, metals and VOCs have been detected below screening criteria since 2000, and no explosives were detected above their respective PALs in 2019. Freon 113 was detected in groundwater in one well in 2019; however, concentrations were below the site characterization PAL, which differs from the screening value used for HHRA. This well (JAW-13) is located near the southern boundary of the NBPs and may represent the northern edge of VOCs observed in groundwater at the WBPA. Given the lack of RDX in groundwater during the current RI, the soil removal that was completed in 1998 is assumed to have removed RDX contamination that could be a source to groundwater.

The HHRA identified potentially unacceptable risks and hazards from exposure to Freon 113 through a potential VI pathway. Therefore, this analyte was identified as a potential VI COC for future hypothetical residents. The ERA concluded that no adverse effects to ecological receptors exist at the NBPs, given the lack of complete exposure pathways for ecological receptors.

6.1.4 NBPLF (IAAP-037G)

Potential sources of contamination at NBPLF include historical activities associated with releases to the surface and subsurface as a result of historical site operations, including burial of waste within the NBPLF. The NBPLF was formerly used for disposal of ash residue from NPB burning operations, as well as flashed cans, containers, and construction debris. The site is no longer an active landfill and is currently used for temporary waste storage, including slightly contaminated explosives waste, which is placed in dumpsters and shipped offsite for disposal at approved facilities.

Based on historical site operations and a comparison of the most current concentration data to site characterization PALs and BTVs, only one explosive (RDX) was identified as a potential site-related chemical of interest in groundwater. RDX contamination has been observed as two small plumes at the NBPLF. The main RDX plume is present at the NBPLF to the east of the former landfill and is restricted to within the shallow bedrock. The second RDX plume is isolated and was historically defined by former overburden well JAW-625. However, RDX was not detected in nearby NBPLF-MW1 during the current RI. Therefore, RDX concentrations in this second plume may have attenuated below the site characterization PAL. Explosives were detected above their site characterization PALs in only three shallow bedrock monitoring wells in 2019 and 2020 (JAW-627, NBPLF-MW4, and NBPLF-MW6). RDX concentrations at JAW-627 have been increasing since 2001. The soil removal that was completed in 1998 is assumed to have removed the bulk of RDX contamination that could be a source to groundwater. Confirmation sampling showed one RDX concentration (2.5 mg/kg) within the former NBPLF above the OU-1 leachability-based RG (1.3 mg/kg). However, the increasing RDX concentrations at JAW-627 indicate there may still be a source of RDX leaching to groundwater from the former landfill. Increasing RDX concentrations may also be indicative of continued plume migration. No RDX was detected in surface water samples collected in 2018, due northeast and southeast of the NBPLF, which indicates that the eastern plume is defined. The RDX is considered to be laterally and vertically delineated for this RI.

The HHRA did not identify any unacceptable risks or hazards for future residential receptors exposed to site-related chemicals in groundwater at the NBPLF. The ERA concluded that no adverse effects to ecological receptors exist at the NBPLF, given the lack of complete exposure pathways for ecological receptors.

6.1.5 FTP (IAAP-039G)

Potential sources of contamination at FTP area include historical activities associated with chemical use, burning, and disposal. The former training pit was used for firefighting training operations between 1982 and 1987. Two smaller pits existed to the north of the main training pit, one disposal pit contained trash and debris, and another pit was used to burn wastes similar to those used in the firefighting practices in the main pit, though this disposal pit was not used for firefighter training.

Based on historical site operations and a comparison of the most current concentration data to site characterization PALs) and BTVs, VOCs, explosives, and arsenic were identified as potential site-related chemicals of interest in groundwater. Numerous VOCs associated with chlorinated solvents, fuels, and associated breakdown products have been detected at the FTP. Historically, 1,1-DCE and 1,1-DCA have exceeded their PALs with the greatest frequency. VOC groundwater contamination is present as one large plume, with the majority of VOC contamination within the footprint of the former main training pit and a soil removal area. The explosives plume is isolated to the sump well (SA-99-1), located within the soil removal area. Arsenic groundwater contamination was observed within the vicinity of the former training pit and soil removal area and arsenic concentrations have been fairly consistent in this area since 2001. The slow groundwater flow velocity and natural attenuation processes are likely helping to limit the extent of plume migration. As such, no contaminant exceedances have been observed in the most downgradient monitoring wells in this area. The VOC plume is considered to be laterally and vertically delineated for this RI.

The HHRA identified potentially unacceptable risks for future residential receptors exposed to site-related chemicals in groundwater at the FTP, including VOCs, explosives, and arsenic. The HHRA also identified potentially unacceptable risks associated with exposure to 1,1-dichloroethane, 1,1-dichloroethene, 1,2-dichloroethane, 4-amino-2,6-dinitrotoluene, arsenic, benzene, cis-1,2-dichloroethane, ethylbenzene, methylene chloride, naphthalene, TCE, and vinyl chloride for site workers and benzene, naphthalene, methyl ethyl ketone, methyl isobutyl ketone, methylene chloride, tetrachloroethene, toluene, TCE, vinyl chloride, m,p-xylene, and o-xylene for construction/utility workers. The ERA concluded that no adverse effects to ecological receptors exist at the FTP, given the lack of complete exposure pathways for ecological receptors.

6.2 Recommendations

it is recommended that the five IAAAP groundwater sites (IAAP-012G, IAAP-032G, IAAP-036G, IAAP-037G, and IAAP-039G) included in this RI report be transferred to a new OU (OU-10). The new OU-10 grouping will include Environmental Restoration sites located within the EDA. Based on the RI conclusions and results of human health risk assessments and ecological risk assessments, the following is also recommended:

- Conduct a Feasibility Study (FS) for three sites (IAAP-032G, IAAP-036G, and IAAP-039G) associated with groundwater at the WBPA, NBPs, and the FTP to evaluate remedial alternatives to address the unacceptable risks or hazards from site-related COCs in groundwater. If appropriate, it is recommended that TCE reductive degradation products (such as cis-1,2-DCE and vinyl chloride) be included in the monitoring plans of the FS remedial alternatives. NFA is warranted for surface water and sediment at the WBPA under IAAP-032G.
- Propose a NFA decision in a Proposed Plan as the preferred remedy for one site (IAAP-012G) associated with groundwater at the EBPs. This recommendation is based on the fact that site-related chemicals do not pose potentially unacceptable risks or hazards. This IAAAP site can subsequently be closed under an NFA Record of Decision for OU-10.
- Conduct a Supplemental Remedial Investigation (SRI) for one site (IAAP-037G). The results of the RI and risk assessments indicate that site-related chemicals do not pose potentially unacceptable risks

or hazards. However, because increasing RDX concentrations have been observed in groundwater at JAW-627 and not all RDX in soil was removed at this site to the OU-1 leachability RG, additional groundwater monitoring at JAW-627 is recommended to provide a further line of evidence that a NFA decision is warranted for the NBPLF.

- Retain the two munition IAAAP sites (IAAP-003-R-01 and IAAP-005-R-01) under OU-5. These two Military Munitions Response Program sites have already been closed as NFA for munitions and explosives of concern (MEC) and munitions chemicals (MC) under the OU-5 ROD (CB&I, 2014); therefore, no additional action is needed for these sites and they can remain closed. These recommendations for the OU-5 sites can be documented in the next five-year review report for IAAAP, which includes the IRP OUs with remedies in place (OU-1, OU-3, OU-4, and OU-5).
- Repair the new EDA staff gauges to obtain accurate measurements in the future. Between staff gauge installation in 2018 and the 2019 RI gauging event, the three new staff gauges (EDA-1 through EDA-3) were damaged.

The RI recommendations are summarized below.

	Army Environmental Database Information	
RI Recommendation	**Site Number**	**Site Name**
FS for groundwater under OU-10	IAAP-036G	North Burn Pads Groundwater
	IAAP-039G	Fire Training Pit Groundwater
FS for groundwater and NFA for surface water and sediment under OU-10	IAAP-032G	West Burn Pad Area Groundwater
NFA for groundwater under OU-10	IAAP-012G	East Burn Pads Groundwater
SRI for groundwater under OU-10	IAAP-037G	North Burn Pad Landfill Groundwater
NFA under OU-5[a]	IAAP-003-R-01	West Burn Pads
	IAAP-005-R-01	West Burn Pads South of Road

[a] NFA is already documented in the OU-5 ROD.

Iowa Army Ammunition Plant, Middletown, Iowa

Site	Active Buildings
East Burn Pads	None
West Burn Pads Area	BG-13
North Burn Pads	None
North Burn Pads Landfill	BG-199-4
Fire Training Pit	None

Attachment 3. VISL Calculator Output

Iowa Army Ammunition Plant, Middletown, Iowa

Default VISL Results

Resident Equation Inputs

Variable	Value
Exposure Scenario	Resident
Temperature for Groundwater Vapor Concentration C	13
ED_{res} (exposure duration) years	26
TR (target risk) unitless	0.000001
THQ (target hazard quotient) unitless	0.1
LT (lifetime) years	70
EF_{res} (exposure frequency) days/year	350
ED_{0-2} (mutagenic exposure duration first phase) years	2
ED_{2-6} (mutagenic exposure duration second phase) years	4
ED_{6-16} (mutagenic exposure duration third phase) years	10
ED_{16-26} (mutagenic exposure duration fourth phase) years	10
EF_{0-2} (mutagenic exposure frequency first phase) days/year	350
EF_{2-6} (mutagenic exposure frequency second phase) days/year	350
EF_{6-16} (mutagenic exposure frequency third phase) days/year	350
EF_{16-26} (mutagenic exposure frequency fourth phase) days/year	350
ET_{res} (exposure time) hours/day	24
ET_{0-2} (mutagenic exposure time first phase) hours/day	24
ET_{2-6} (mutagenic exposure time second phase) hours/day	24
ET_{6-16} (mutagenic exposure time third phase) hours/day	24
ET_{16-26} (mutagenic exposure time fourth phase) hours/day	24
AF_{gw} (Attenuation Factor Groundwater) unitless	0.001
AF_{ss} (Attenuation Factor Sub-Slab) unitless	0.03

Attachment 3. VISL Calculator Output—Resident Vapor Intrusion Screening Levels (VISL)

Iowa Army Ammunition Plant, Middletown, Iowa

Chemical	CAS Number	Does the chemical meet the definition for volatility? (HLC>1E-5 or VP>1)	Does the chemical have inhalation toxicity data? (IUR and/or RfC)	Is Chemical Sufficiently Volatile and Toxic to Pose Inhalation Risk Via Vapor Intrusion from Soil Source? ($C_{vp} > C_{i,a}$,Target?)	Is Chemical Sufficiently Volatile and Toxic to Pose Inhalation Risk Via Vapor Intrusion from Groundwater Source? ($C_{hc} > C_{i,a}$,Target?)	Target Indoor Air Concentration (TCR=1E-06 or THQ=0.1) MIN($C_{ia,c}$,$C_{ia,nc}$) (µg/m^3)	Toxicity Basis	Target Sub-Slab and Near-source Soil Gas Concentration (TCR=1E-06 or THQ=0.1) C_{sg},Target (µg/m^3)	Target Groundwater Concentration (TCR=1E-06 or THQ=0.1) C_{gw},Target (µg/L)	Is Target Groundwater Concentration < MCL? (C_{gw} < MCL?)	Pure Phase Vapor Concentration C_{vp} (13 ºC) (µg/m^3)

	SA-SED	Skin Surface Area Available for Contact - Sediment	cm^2	7,567	EPA, 2011 (7)	7,567	EPA, 2014 (9)
	SSAF	Soil / Sediment-to-Skin Adherence Factor	mg/cm^2-day	0.07	EPA, 2014 (2)	0.07	EPA, 2014 (9)
	ET	Exposure Time	hours/day	2	(8)	2	(8)
Surface Water	IR-SW	Ingestion Rate of Water While Wading / Swimming	L/hour	0.021 / 0.092	EPA, 2019 (10)	0.021 / 0.092	EPA, 2019 (10)
	SA-w	Skin Surface Area Available for Contact - Wading	cm^2	7,567	EPA, 2011 (7)	7,567	EPA, 2011 (4)
	SA-s	Skin Surface Area Available for Contact - Swimming	cm^2	19,652	EPA, 2011 (11)	19,652	EPA, 2011 (4)
	ET	Exposure Time	hour/event	2	(8)	2	(8)
	t_{event}	Event Time	hour/event	2	(8)	2	(8)
	EV	Event Frequency	events/day	1	(8)	1	(8)

Notes;
(1) Exposure duration of 26 days/year is based on the assumption that hunting/recreation would occur 1 day/week during the approximately 6 months when the average temperature is above 32°F.
(2) Default exposure factor value for adult residents was used for hunters/recreators.
(3) Exposure duration of 8 years is based on adolescents aged 8 to 16 years of age. As described in the Hunting and Fishing Regulation of the Iowa Army Ammunition Plant Regulation 420-1 (August 2019), observers as young as 8 years old could be present at IAAAP.
(4) Adolescent body weight of 44.3 kg recommented by EPA.
(5) Calculated as the product of ED (years) x 365 days/year.
(6) Calculated as the product of 70 years assumed human lifetime (EPA, 2014) x 365 days/year.
(7) Weighted average of mean values for head, hands, forearms, lower legs, and feet (male and female, 21+ years), Tables 7-2 and 7-12 from Exposure Factors Handbook (EPA, 2011).
(8) Exposure time of 2 hours/day (or 2 hours/event with 1 event/day) is based on professional judgment.
(9) Consistent with the approach in the RSL User's Guide (EPA, 2023), exposure factors for adult recreators were used for adolescent recreators.
(10) Ingestion rate while wading (0.021 L/hr) is the value recommended by the EPA in the letter dated 15 Aug 2018 regarding the Response to Comments on the Uniform Federal Policy – Quality Assurance Project Plan (UFP-QAPP), Packet #3. The ingestion rate while swimming (0.092 L/hr) is the 95th percentile ingestion rate for swimming for ages 21+ years (EPA, 2019a).
(11) Weighted average of mean values for male and female adults, 21-78, Table 7.9 from Exposure Factors Handbook (EPA, 2011).

TABLE 1

SELECTION OF EXPOSURE PATHWAYS

East Burn Pads

Iowa Army Ammunition Plant, Middletown, Iowa

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	On-Site/ Off-Site	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Current/Future	Soil	Soil	Soil	Hunter/Recreator	Adult, Adolescent	Dermal, Ingestion, Inhalation	On-site	None	The East Burn Pads is open to recreational use; therefore, hunting is permitted at the site. However, soil is addressed under OU1 with land use controls for industrial land use.
	Surface Water/Sediment	Surface Water/Sediment	Drainage Ditches	Hunter/Recreator	Adult, Adolescent	Dermal, Ingestion	On-site	None	The East Burn Pads is open to recreational use; therefore, hunting is permitted at the site. However, the waterbodies within the East Burn Pads are intermittent in nature, thus surface water and sediment were not evaluated in the HHRA. Exposures to Spring Creek surface water and sediment are addressed with the West Burn Pads HHRA.
Future	Soil	Soil	Soil	Site Worker	Adult	Dermal, Ingestion, Inhalation	On-site	None	Soil is addressed under OU1 with land use controls for industrial land use.
				Construction/ Utility Worker	Adult	Dermal, Ingestion, Inhalation	On-site	None	
				Hypothetical Resident	Adult, Child	Dermal, Ingestion, Inhalation	On-site	None	
	Groundwater(1)	Tapwater	Tapwater	Site Worker	Adult	Dermal, Ingestion	On-site	Quant (2)	Future site workers could use groundwater as a potable water source. Site workers could ingest drinking water and could have dermal contact with groundwater while hand washing.
				Hypothetical Resident	Adult, Child	Dermal, Ingestion	On-site	Quant	Future hypothetical residents could use groundwater as a potable water source. Residents could ingest drinking water and could have dermal contact with groundwater while showering.
		Household Air (Domestic Use)	Vapors in House (Domestic Use)	Hypothetical Resident	Adult, Child	Inhalation	On-site	Quant	Future hypothetical residents could be exposed to vapors in household air via inhalation.
		Indoor Air (Vapor Intrusion)	Indoor Air (Vapor Intrusion)	Hypothetical Resident	Adult, Child	Inhalation	On-Site	Quant	Future hypothetical residents could inhale volatile groundwater constituents in indoor air from vapor intrusion.
				Site Worker	Adult	Inhalation	On-site	Quant (2)	Site workers could inhale volatile groundwater constituents in indoor air from vapor intrusion.
	Shallow Groundwater	Shallow Groundwater	Shallow Groundwater in Trench	Construction/ Utility Worker	Adult	Dermal, Ingestion	On-site	Quant (2)	Construction/utility workers could incidentally ingest and have dermal contact with shallow groundwater in a trench while replacing the culverts within the East Burn Pads.
		Trench Air	Vapors in a Trench	Construction/ Utility Worker	Adult	Inhalation	On-site	Quant (2)	Construction/utility workers could inhale volatile groundwater constituents in trench air while replacing culverts within the East Burn Pads.

Notes:
Quant: Quantitative evaluation

(1) Groundwater is not currently being used as a potable water source and there are no plans to use groundwater for potable purposes in the future; however, based on applicable CERCLA policy and guidance, groundwater at the East Burn Pads is classified as Class IIB, a potential source of drinking water. Therefore, the HHRA evaluates potential exposures to groundwater due to its potential future use as a drinking water source. This requires the evaluation of future residential exposures to groundwater.

(2) Potential exposures to groundwater were not estimated for a site worker and construction worker because the estimated risks for a hypothetical residential scenario did not exceed acceptable risk levels and COCs were not identified for a residential scenario. The hypothetical resident exposures and potential health risks and hazards are considered protective of other receptors.

Notes:

(1) Maximum concentration is used for screening.

(2) Source: *Evaluation of Background Concentrations of Metals in Groundwater, Iowa Army* Ammunition Plant, *Middletown, Iowa*. Prepared for U.S. Army Corps of Engineers Louisville District (CH2M, February 2020).

(3) Regional Screening Levels (RSL) for Tap Water (May, 2023). Concentrations based on non-carcinogenic health effects are based on HQ=0.1.
The RSL for hexavalent chromium was used for total chromium.
The RSL for mercuric chloride (and other mercury salts) was used for mercury.

(4) Values are the Federal Maximum Contaminant Levels (MCLs) and if no MCL was available, the EPA's (March 2018) Office of Water Lifetime Health Advisory (LHA) was provided.

(5) Rationale Codes
Selection Reason: Above Screening Levels (ASL)
Deletion Reason: Below Screening Level (BSL)
No Toxicity Information (NTX)
Essential Nutrient (NUT)

ARAR/TBC = Applicable or Relevant and Appropriate Requirement/ To Be Considered
B = Inorganic, metals results detected below the RL. The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
ca = carcinogenic
COPC = Chemical of Potential Concern
DNX = 1,3-dinitroso-5-nitro-1,3,5-triazacyclohexane
HQ = hazard quotient
HMX = Hot Melt Explosive
J = compound was detected below the reporting limit in the sample
MNX = 1-Nitroso-3,5-dinitro-1,3,5-triazacyclohexane
NA = not available
nc = noncarcinogenic
RDX = Royal Demolition Explosive
µg/L= microgram per liter

Notes:

(1) Maximum concentration is used for screening.

(2) Source: *Evaluation of Background Concentrations of Metals in Groundwater, Iowa Army* Ammunition Plant, *Middletown, Iowa*. Prepared for U.S. Army Corps of Engineers Louisville District (CH2M, February 2020).

(3) Residential Groundwater Vapor Intrusion Screening Level (May 2023). Concentration based on site specific groundwater temperature of 13°C and non-carcinogenic health effects are based on HQ=0.1.

(4) Rationale Codes:

Selection Reason: Above Screening Levels (ASL)

Deletion Reason: Below Screening Level (BSL)

Not Sufficiently Volatile (NSV)

No Toxicity Information (NTX)

Essential Nutrient (NUT)

ARAR/TBC = Applicable or Relevant and Appropriate Requirement/ To Be Considered

B = Inorganic, metals results detected below the RL. The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.

COPC = Chemical of Potential Concern

DNX = 1,3-dinitroso-5-nitro-1,3,5-triazacyclohexane

HQ = hazard quotient

HMX = Hot Melt Explosive

J = compound was detected below the reporting limit in the sample

MNX = 1-Nitroso-3,5-dinitro-1,3,5-triazacyclohexane

NA = not available

nc = noncarcinogenic

RDX = Royal Demolition Explosive

µg/L= microgram per liter

TABLE 3.1.RME
MEDIUM-SPECIFIC EXPOSURE POINT CONCENTRATION SUMMARY
REASONABLE MAXIMUM EXPOSURE
East Burn Pads
Iowa Army Ammunition Plant, Middletown, Iowa

Scenario Timeframe: Future (Hypothetical Resident)
Medium: Groundwater (RDX Plume)
Exposure Medium: Tapwater

Exposure Point	Chemical of Potential Concern	Units	Arithmetic Mean*	95% UCL (Distribution)	Maximum Concentration (Qualifier)	Exposure Point Concentration **			
						Value	Units	Statistic	Rationale
Tapwater East Burn Pads RDX Plume	4-Amino-2,6-dinitrotoluene	µg/L	3.2E-01	NA	3.2E-01	3.2E-01	µg/L	Sitewide Max	1
	RDX	µg/L	1.7E+01	NA	4.7E+01	4.7E+01	µg/L	Plume Max	1
	Arsenic	µg/L	1.3E+01	NA	2.8E+01	2.8E+01	µg/L	Sitewide Max	1
	Barium	µg/L	1.3E+02	NA	6.1E+02	6.1E+02	µg/L	Sitewide Max	1

	Cobalt	µg/L	3.8E+00	NA	3.8E+00 B	3.8E+00	µg/L	Plume Max	1
	Manganese	µg/L	8.5E+01	NA	8.5E+01	8.5E+01	µg/L	Plume Max	1
	Trichloroethene	µg/L	2.5E+00	NA	3.0E+00 J	3.0E+00	µg/L	Sitewide Max	1

Notes:
** Groundwater EPCs were calculated using monitoring wells located within the core of the RDX plume: EBP-MW3, EBP-MW4, EBP-MW5, EBP-MW6, EBP-MW7, EDA-2, and JAW-614. The maximum detected concentrations for 4-amino-2,6-dinitrotoluene, arsenic, barium, chromium, and trichloroethene were outside the core of the RDX plume; therefore, the EPCs for these constituents were the maximum detected concentrations based on the sitewide groundwater dataset.

Statistics: Max - Maximum Detected Value

* Arithmetic mean of detected concentrations are presented.

Rationale:
(1) The maximum detected concentration was used as the EPC because there were less than 4 detected concentrations or less than 8 samples from the plume.

µg/L = microgram per liter
B = Inorganic, metals results detected below the RL. The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
EPC = Exposure Point Concentration
J = compound was detected below the reporting limit in the sample
NA = Not Available
RME = Reasonable Maximum Exposure
UCL = Upper Confidence Limit

TABLE 3.2.RME
MEDIUM-SPECIFIC EXPOSURE POINT CONCENTRATION SUMMARY
REASONABLE MAXIMUM EXPOSURE
East Burn Pads

Scenario Timeframe: Future (Hypothetical Resident)
Medium: Groundwater
Exposure Medium: Indoor Air (Vapor Intrusion)

Exposure Point	Chemical of Potential Concern	Units	Arithmetic Mean*	95% UCL (Distribution)	Maximum Concentration (Qualifier)	Exposure Point Concentration			
						Value	Units	Statistic	Rationale
Indoor Air (Vapor Intrusion)	Trichloroethene	µg/L	2.5E+00	NA	3.0E+00 J	3.0E+00	µg/L	Sitewide Max	1

Notes:
Statistics: Max - Maximum Detected Value

* Arithmetic mean of detected concentrations are presented.

(1) The maximum detected concentration was used as the EPC to evaluate the vapor intrusion pathway.

EPC = Exposure Point Concentration
J = result is estimated
NA = not applicable
UCL = Upper Confidence Limit
µg/L = microgram per liter

TABLE 3.2.RME SUPPLEMENT
MEDIUM-SPECIFIC EXPOSURE POINT CONCENTRATION SUMMARY
REASONABLE MAXIMUM EXPOSURE
East Burn Pads
Iowa Army Ammunition Plant, Middletown, Iowa

Scenario Timeframe: Future (Hypothetical Resident)
Medium: Groundwater
Exposure Medium: Indoor Air (Vapor Intrusion)

Exposure Point	Chemical of Potential Concern (1)	Exposure Point Concentration in Groundwater		Exposure Point Concentration in Indoor Air	
		Value (2)	Units	Value (3)	Units
Indoor Air (Vapor Intrusion)	Trichloroethene	3.0E+00	µg/L	7.0E-01	$\mu g/m^3$

Notes:
(1) Chemicals of Potential Concern from Table 2.2.RME.
(2) Selection of exposure point concentration from Table 3.2.RME.
(3) The indoor air concentrations for groundwater-to-indoor air were estimated using the EPA's VISL Calculator, May 2023 (EPA, 2023).
Site-specific groundwater temperature of 13 degrees C used to estimate indoor air concentrations.

µg/L = microgram per liter
$\mu g/m^3$ = microgram per cubic meter

Note:

(1) Source: Risk Assessment Guidance for Superfund. Volume 1: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. Section 4.2 and Exhibit 4-1. USEPA recommends that the oral RfD should not be adjusted to estimate the absorbed dose for compounds when the absorption efficiency is greater than 50%. Constituents that do not have oral absorption efficiencies reported on this table were assumed to have an oral absorption efficiency of 100%.

(2) Adjusted based on RAGS Part E.

(3) The RfD (0.14 mg/kg-day) presented in IRIS includes manganese from all sources, including diet. This RfD was adjusted by subtracting the dietary contribution from the normal U.S. diet (an upper limit of 5 mg/day) and applying a modifying factor of 3 to address uncertainties associated with non-food manganese exposure sources.

(1) Source: Risk Assessment Guidance for Superfund. Volume 1: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. Section 4.2 and Exhibit 4-1. USEPA recommends that the oral slope factor should not be adjusted to estimate the absorbed dose for compounds when the absorption efficiency is greater than 50%. Constituents that do not have oral absorption efficiencies reported on this table were assumed to have an oral absorption efficiency of 100%.

(2) Adjusted based on RAGS Part E.

(3) This chemical operates with a mutagenic mode of action (EPA, 2005) and would exhibit a greater effect in early-life versus later-life exposure. Chemical-specific toxicity data are not available for childhood and early-life exposures; thus, EPA (2005) default age-dependent adjustment factors (ADAF) will be applied to the slope factor as follows:

AGE	AGE ADAF
0-<2	10
2-<16	3
16-<26	1

Definitions:
Cal EPA = California Environmental Protection Agency
IRIS = Integrated Risk Information System
NA = Not Available

Weight of Evidence definitions (EPA, 1986):

Group A chemicals (known human carcinogens) are agents for which there is sufficient evidence to support the causal association between exposure to the agents in humans and cancer.

Group B1 chemicals (probable human carcinogens) are agents for which there is limited evidence of possible carcinogenicity in humans.

Group C chemicals (possible human carcinogens) are agents for which there is limited evidence of carcinogenicity in animals and inadequate or a lack of human data.

Group D chemicals (not classifiable as to human carcinogenicity) are agents with inadequate human and animal evidence of carcinogenicity or for which no data are available.

Inorganics: DAevent (mg/cm^2-event) =

DA_{event} = Kp x CW x tevent x 0.001 mg/ug x 0.001 l/cm^3 (Eq 1)

Organics: DAevent (mg/cm^2-event) =

DA_{event} = $t_{event} \leq t^*$: DA_{event} (mg/cm^2-event) =
2 x FA x Kp x Cw x (sqrt((6 x τ x t_{event}) / (3.1415))) x CF1 x CF2 (Eq 2)

$t_{event} > t^*$: DA_{event} (mg/cm^2-event) =
FA x Kp x CW x (t_{event}/(1+B) + 2 x τ x ((1 + 3B + $3B^2$)/$(1+B)^2$)) xCF1 x CF2 (Eq 3)

Notes:
Values for permeability constants, B, tau, t*, and FA are from EPA 2004, *Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment - Final).* EPA/540/R/99/005.
B - Dimensionless ratio of the permeability coefficient of a compound through the stratum corneum relative to its permeability coefficient across the viable epidermis (dimensionless).
cm/hr - centimeter per hour
hr - hour
mg/cm^2-event - milligram per square centimeter per event
µg/L - microgram per liter
NA - Not applicable
t* - Time to reach steady-state
CF1 - Conversion Factor 1 (0.001 mg/µg), CF2 - Conversion Factor 2 (0.001 L/cm^3)

Notes:

(1) Carcinogenic risks were estimated for trichloroethene by summing the risks for two different approaches: 1) Using the oral CSF factor for kidney cancer, which has a mutagenic mode of action (calculated in Table 7.3 RME Supplement A), and 2) using the CSF for non-Hodgkin lymphoma (NHL) and liver cancer.

(2) Intakes and exposure concentrations using the toxicity values for the kidney component of TCE were estimated on Table 7.3 RME Supplement A.

CSF = Cancer slope factor

µg/L = microgram per liter

mg/m^3= milligram per cubic meter

mg/kg/day = milligram per kilogram per day

2 x FA x Kp x Cw x (sqrt((6 x τ x t_{event}) / (3.1415))) x CF1 x CF2 (Eq 2)

$t_{event} > t^*$: DA_{event} (mg/cm^2-event) =
FA x Kp x CW x (t_{event}/(1+B) + 2 x τ x ((1 + 3B + $3B^2$)/$(1+B)^2$)) xCF1 x CF2 (Eq 3)

Notes:
Values for permeability constants, B, tau, t*, and FA are from EPA 2004, *Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment - Final).* EPA/540/R/99/005.
B - Dimensionless ratio of the permeability coefficient of a compound through the stratum corneum relative to its permeability coefficient across the viable epidermis (dimensionless).
cm/hr - centimeter per hour
hr - hour
mg/cm^2-event - milligram per square centimeter per event
µg/L - microgram per liter
NA - Not applicable
t* - Time to reach steady-state
CF1 - Conversion Factor 1 (0.001 mg/µg), CF2 - Conversion Factor 2 (0.001 L/cm^3)

			Exp. Route Total								3E-06

Notes:

(1) Carcinogenic risks were estimated for trichloroethene by summing the risks for two different approaches: 1) Using the oral CSF factor for kidney cancer, which has a mutagenic mode of action (calculated in Table 7.9 RME Supplement A), and 2) using the CSF for non-Hodgkin lymphoma (NHL) and liver cancer.

(2) Intakes and exposure concentrations using the toxicity values for the kidney component of TCE were estimated on Table 7.9 RME Supplement A.

CSF = Cancer slope factor

µg/L = microgram per liter

mg/m^3= milligram per cubic meter

mg/kg/day = milligram per kilogram per day

Notes:

(1) The data were reduced such that when a normal and duplicate sample were available, the highest detected concentration among normal or duplicate samples was used when a chemical was detected in any sample. If both results were non-detect, the lowest reported detection limit (i.e., reporting limit) was used.

NA = Not available

WG - groundwater

B - Inorganic, metals results detected below the RL. The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.

J - compound was detected below the reporting limit in the sample

= - detected
U - not detected
µg/L - microgram per liter

Non-detected Data Analysis: East Burn Pads

Chemicals that were 100 percent non-detected (ND) in groundwater were not identified as COPCs for groundwater; however, a qualitative evaluation of the 100 percent (%) ND chemicals within East Burn Pads (EBP) was conducted.

Detection limits (DLs) and reporting limits (RLs) for chemicals that were 100 % ND were compared to groundwater screening levels (SLs). Groundwater SLs are the USEPA Regional Screening levels (RSLs) for tap water (USEPA, 2023) using an excess lifetime cancer risk (ELCR) of $1x10^{-6}$ and a hazard quotient (HQ) of 1. The EBP ND chemicals and a comparison of the ND DLs and RLs to SLs is provided in Attachment 3 (Table 1). ND chemicals exceeding SLs are identified and discussed below with regard to the adequacy of DLs/RLs and potential to be related to former site activities.

Non-detected Chemicals Exceeding Screening Levels

Five explosives (2,4-dinitrotoluene, 2,6-dinitrotoluene, 2-nitrotoluene, 3-nitrotoluene, and nitrobenzene), one metal (thallium), one polycyclic aromatic hydrocarbon ([PAH], naphthalene), 13 semi-volatile organic compounds (SVOCs), and 18 volatile organic compounds (VOCs), have DLs and/or RLs exceeding SLs at the EBP. With the exception of 3-nitrotoluene, all ND chemicals with RLs greater than SLs also had DLs greater than SLs. Explosives with RLs and/or DLs greater than SLs had a dataset of 22 samples per explosive. Thallium and naphthalene were only analyzed in one sample each in the groundwater dataset. SVOCs with RLs and/or DLs greater than SLs had a data set of 12, 15, 17 or 18 samples per SVOC. VOCs with RLs and/or DLs greater than SLs had a data set of 20 samples per VOC with the exceptions of 1,1,1,2-tetrachloroethane, 1,2,3-trichloropropane, 1,2-dibromo-3-chloropropane and 1,2-dibromoethane which were only sampled once in the groundwater data set.

One explosive (TNX), 9 SVOCs (1,3-dichlorobenzene, 1,4-oxathiane, 2-nitrophenol, 3-nitroanaline, 4-bromophenyl phenyl ether, 4-chlorophenyl phenyl ether, 4-nitrophenol, carbazole and dimethyl phthalate) and 6 VOCs (1,1-dichloropropene, 1-chlorohexane, 2,2-dichloropropane, 4-isopropyltoluene, ethane and ethene) were consistently ND in the EBP data set, but SLs were not available for these ND chemicals. Therefore, those ND chemicals were not included in the ND assessment process.

Non-detected Chemicals Related to Former Site Activities

To determine whether ND data exceeding SLs could potentially be related to former site activities, the historical IAAAP facility-wide dataset for the non-Formerly Utilized Sites Remedial Action Program (FUSRAP) sites was evaluated, and results are provided in Attachment 3 (Table 2). The ND comparison included historically detected chemicals in all media; however, surface water and sediment are not an issue/present at EBP and soil is being addressed under the Operable Unit 1 Remedial Action.

- **ND Explosives**: 2,4-dinitrotoluene, 2,6-dinitrotoluene, 2-nitrotoluene and nitrobenzene have been historically detected in groundwater, soil and surface water at IAAAP, and with the exception of 2-nitrotoluene and 3-nitrotoluene, all have been historically detected in sediment at IAAAP. It is noted that DLs (ranging from 0.089 to 0.86 ug/L) and RLs (ranging from 0.11 to 2 ug/L) for the 5 explosives with DLs or RLs greater than SLs are acceptably low for an explosives analysis. Additionally, when compared to the other ND explosive with DLs and RLs less than SLs, the SLs for the 5 ND explosives with DLs or RLs greater than SLs have the lowest SLs. As a result, having acceptably low DLs and RLs for explosives analysis, it is highly probable that the ND explosives with DLs or RLs greater than SLs are due to the relatively higher toxicity of these 5 explosives in comparison to the other analyzed ND explosives, and it is unlikely that any of the ND explosives are present in site groundwater.

- **ND Metals:** Thallium has been historically detected in soil, surface water and sediment at IAAAP, but not in groundwater. DLs for the ND metals are typical of an EPA SW 846 Method 6010 analysis (USEPA, 2014) where several other (18) metals have been detected (see Attachment 1 Table 2.1). Additionally, when compared to the other ND metals that did not have RLs or DLs greater than SLs, thallium has the lowest SL (0.2 ug/L) which is one to two orders of magnitude lower than the other ND metal SLs. The thallium oral RfD of $1x10^{-5}$ mg/kg-day in the RSL table is a provisional toxicity value presented in an appendix to the main Provisional Peer Reviewed Toxicity Value (PPRTV) document (USEPA, 2012). Due to the lack of availability of suitable human studies noted in the main document, USEPA decided that it was inappropriate to derive a chronic PPRTV for thallium and instead presented the oral RfD value as a screening toxicity value in an appendix. USEPA warns that users of screening toxicity values in an appendix to a PPRTV assessment should understand that there is considerably more uncertainty associated with the derivation of a supplemental screening toxicity value than for a value presented in the body of the PPRTV assessment. Due to the high level of uncertainty associated with this value, risks associated with thallium are typically evaluated qualitatively as opposed to calculating numerical risk estimations.

- **ND PAHs and SVOCs**: The one PAH with DLs and RLs greater than the SL (naphthalene), has been historically detected in groundwater, soil and sediment at IAAAP. None of the 13 SVOCs with RLs and/or DLs greater than SLs have been historically detected in sediment or surface water at IAAAP. Eight of the 13 SVOCs with RLs and/or DLs greater than SLs were historically detected in groundwater at IAAAP and all 13 of the SVOCs were historically detected in soil at IAAAP. As noted in Attachment 1, Table 2.1, only one SVOC (bis[2ethylhexyl]phthalate) was detected in the SVOC groundwater data set, and only detected twice out of 17 samples and at levels less than the SL. Additionally, the maximum DL for all 13 of the ND SVOCs with RLs and/or DLs greater than SLs was 5 ug/L which is an acceptably low DL for SVOC analysis. Based on the low DLs and RLs for the one PAH and 13 SVOC ND chemicals, it is highly probable that the ND PAH/SVOCs with DLs and/or RLs greater than SLs are due to the relatively higher toxicity of these chemicals in comparison to the 24 other analyzed ND SVOCs with screening levels, and it is unlikely that any of the ND SVOCs are present in site groundwater.

- **ND VOCs**: Of the 18 VOCs with RLs and DLs greater than SLs, 12 have been historically detected in groundwater at IAAAP, 6 have been historically detected in soil at IAAAP, 8 have been historically detected in surface water at IAAAP, and 2 have been historically detected in sediment at IAAAP. Although 7 VOCs were detected in the groundwater data set (Attachment 1, Table 2.1), only one VOC was detected above the SL (trichloroethene) and only detected twice out of 20 samples with a maximum DL of 3 ug/L. Similar to the detected VOCs, the 18 ND VOCs with RLs and DLs greater than SLs had acceptably low RLs and DLs, with the maximum RL of the 18 ND VOCs being 5 ug/L and the maximum DL being 3 ug/L. With no evidence of chemical interferences and consistently low RLs and DLs for both detected and ND VOCs, the ND VOCs with RLs and DLs greater than SLs are likely a result of the lower SLs/higher toxicity associated with the 18 ND VOCs, and none of the ND VOCs are likely present in site groundwater.

Conclusions

Five explosives (2,4-dinitrotoluene, 2,6-dinitrotoluene, 2-nitrotoluene, 3-nitrotoluene, and nitrobenzene), one metal (thallium), one PAH (naphthalene), 13 SVOCs, and 18 VOCs have DLs and/or

RLs exceeding SLs at the EBP. Although the DLs and/or RLs for these ND chemicals are greater than the SLs, based on the adequacy of DLs/RLs and comparison to historically detected chemicals in groundwater at IAAAP, further consideration of ND chemicals does not appear warranted in the EBP HHRA.

Notes:
(1) Regional Screening Levels (RSLs) for Chemical Contaminants at Superfund Sites (May 2023) - Tapwater. Concentrations based on non-carcinogenic health effects are based on HQ=1; carcinogenic effects are based on risk of 1E-06. Available: https://www.epa.gov/risk/regional-screening-levels-rsls-generic-tables
1,3-Dichloropropene was used as a surrogate for cis-1,3-Dichloropropene
1,3-Dichloropropene was used as a surrogate for trans-1,3-Dichloropropene
Xylenes, total was used as a surrogate for Xylene, m,p-
[2] The maximum detection limit and reporting limit were compared to the screening level.

FOD = frequency of detect
ug/L = microgram per liter
NA = not available

TABLE 1

SELECTION OF EXPOSURE PATHWAYS

West Burn Pads Area

Iowa Army Ammunition Plant, Middletown, Iowa

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	On-Site/ Off-Site	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Current/Future	Soil	Soil	Soil	Hunter/Recreator	Adult, Adolescent	Dermal, Ingestion, Inhalation	On-site	None	The West Burn Pads is open to recreational use; therefore, hunting is permitted at the site. However, soil is addressed under OU1 with land use controls for industrial land use.
	Surface Water	Surface Water	Spring Creek	Hunter/Recreator	Adult, Adolescent	Dermal, Ingestion	On-site	Quant	The West Burn Pads is partially open to recreational use; therefore, hunting is permitted at the site. The HHRA includes surface water and sediment data for the Explosives Disposal Area.
	Sediment	Sediment	Spring Creek	Hunter/Recreator	Adult, Adolescent	Dermal, Ingestion	On-site	Quant	The West Burn Pads is partially open to recreational use; therefore, hunting is permitted at the site. The HHRA includes surface water and sediment data for the Explosives Disposal Area.
	Groundwater	Indoor Air (Vapor Intrusion)	Indoor Air (Vapor Intrusion)	Site Worker	Adult	Inhalation	On-site	Quant (2)	Site workers could inhale volatile groundwater constituents in indoor air from vapor intrusion.
Future	Soil	Soil	Soil	Site Worker	Adult	Dermal, Ingestion, Inhalation	On-site	None	Soil is addressed under OU1 with land use controls for industrial land use.
				Construction/ Utility Worker	Adult	Dermal, Ingestion, Inhalation	On-site	None	
				Hypothetical Resident	Adult, Child	Dermal, Ingestion, Inhalation	On-site	None	
	Groundwater(1)	Tapwater	Tapwater	Site Worker	Adult	Dermal, Ingestion	On-site	Quant (2)	Future site workers could use groundwater as a potable water source. Site workers could ingest drinking water and could have dermal contact with groundwater while hand washing.
				Hypothetical Resident	Adult, Child	Dermal, Ingestion	On-site	Quant	Future hypothetical residents could use groundwater as a potable water source. Residents could ingest drinking water and could have dermal contact with groundwater while showering.
		Household Air (Domestic Use)	Vapors in House (Domestic Use)	Hypothetical Resident	Adult, Child	Inhalation	On-site	Quant	Future hypothetical residents could be exposed to vapors in household air via inhalation.
		Indoor Air (Vapor Intrusion)	Indoor Air (Vapor Intrusion)	Hypothetical Resident	Adult, Child	Inhalation	On-Site	Quant	Future hypothetical residents could inhale volatile groundwater constituents in indoor air from vapor intrusion.
	Shallow Groundwater	Shallow Groundwater	Shallow Groundwater in Trench	Construction/ Utility Worker	Adult	Dermal, Ingestion	On-site	Quant (2)	Construction/utility workers could incidentally ingest and have dermal contact with shallow groundwater in a trench while replacing the culverts within the West Burn Pads.
		Trench Air	Vapors in a Trench	Construction/ Utility Worker	Adult	Inhalation	On-site	Quant (2)	Construction/utility workers could inhale volatile groundwater constituents in trench air while replacing culverts within the West Burn Pads.

Notes:
Quant: Quantitative evaluation

(1) Groundwater is not currently being used as a potable water source and there are no plans to use groundwater for potable purposes in the future; however, based on applicable CERCLA policy and guidance, groundwater at the West Burn Pads is classified as Class IIB, a potential source of drinking water. Therefore, the HHRA evaluates potential exposures to groundwater due to its potential future use as a drinking water source. This requires the evaluation of future residential exposures to groundwater.

(2) Potential exposures to groundwater are only estimated for a site worker and construction worker if the estimated risks for a hypothetical residential scenario exceed acceptable risk levels and COCs are identified for a residential scenario.

Notes:

(1) Maximum concentration is used for screening.

(2) Source: *Evaluation of Background Concentrations of Metals in Sediment and Surface Water, Iowa Army Ammunition Plant, Middletown, Iowa*. Prepared for U.S. Army Corps of Engineers Louisville District (CH2M, July 2020).

(3) Regional Screening Levels for Recreational Surface Water (May 2023). Concentrations based on non-carcinogenic health effects are based upon HQ=0.1.

(4) Rationale Codes

Deletion Reason: Below Screening Level (BSL)
Essential Nutrient (NUT)

ARAR/TBC = Applicable or Relevant and Appropriate Requirement/ To Be Considered
ca = carcinogenic
COPC = Chemical of Potential Concern
HQ = hazard quotient
HMX = Hot Melt Explosive
J = compound was detected below the reporting limit in the sample
NA = not available
nc = noncarcinogenic
RDX = Royal Demolition Explosive
µg/L= microgram per liter

Notes:

(1) Chemicals without a reported detection range are due to 100% of the chemical's results being detected and detected chemical results did not report detection limits.

(2) Maximum concentration is used for screening.

(3) Source: *Evaluation of Background Concentrations of Metals in Sediment and Surface Water, Iowa Army Ammunition Plant, Middletown, Iowa*. Prepared for U.S. Army Corps of Engineers Louisville District (CH2M, July 2020).

(4) Regional Screening Levels for Recreational Sediment (May 2023). Concentrations based on non-carcinogenic health effects are based upon HQ=0.1.
The RSL for Chromium(VI) was used for Chromium, total.

(5) Rationale Codes
Deletion Reason: Below Screening Level (BSL)
Essential Nutrient (NUT)

ARAR/TBC = Applicable or Relevant and Appropriate Requirement/ To Be Considered
ca = carcinogenic
COPC = Chemical of Potential Concern
HQ = hazard quotient
J = compound was detected below the reporting limit in the sample
L = lead action level
mg/kg = milligram per kilogram
NA = not available
nc = noncarcinogenic

TABLE 2.3
OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN
West Burn Pads Area
Iowa Army Ammunition Plant, Middletown, Iowa

Scenario Timeframe: Future (Site Worker and Hypothetical Resident)
Medium: Groundwater
Exposure Medium: Tapwater/Household Air (Domestic Use)

Notes:

(1) Maximum concentration is used for screening.

(2) Source: *Evaluation of Background Concentrations of Metals in Groundwater, Iowa Army* Ammunition Plant, *Middletown, Iowa*. Prepared for U.S. Army Corps of Engineers Louisville District (CH2M, February 2020).

(3) Regional Screening Levels (RSL) for Tap Water (May 2023). Concentrations based on non-carcinogenic health effects are based on HQ=0.1.

(4) Values are the Federal Maximum Contaminant Levels (MCLs) and if no MCL was available, the EPA's (March 2018) Office of Water Lifetime Health Advisory (LHA) was provided.

(5) Rationale Codes

Selection Reason: Above Screening Levels (ASL)
Deletion Reason: Below Screening Level (BSL)
No Toxicity Information (NTX)

ARAR/TBC = Applicable or Relevant and Appropriate Requirement/ To Be Considered
ca = carcinogenic
COPC = Chemical of Potential Concern
DNX = 1,3-Dinitro-5-nitroso-1,3,5-triazinane
HQ = hazard quotient
HMX = Hot Melt Explosive
L = federal action level
J = compound was detected below the reporting limit in the sample
MNX = 1-Nitroso-3,5-dinitro-1,3,5-triazacyclohexane
NA = not available
nc = noncarcinogenic
RDX = Royal Demolition Explosive
TNX = Hexahydro-1,3,5-trinitroso-1,3,5-triazine
µg/L= microgram per liter

Notes:

(1) Maximum concentration is used for screening.

(2) Source: *Evaluation of Background Concentrations of Metals in Groundwater, Iowa Army* Ammunition Plant, *Middletown, Iowa* . Prepared for U.S. Army Corps of Engineers Louisville District (CH2M, February 2020).

(3) Residential Groundwater Vapor Intrusion Screening Level (May 2023). Concentration based on site specific groundwater temperature of 13°C and non-carcinogenic health effects are based on HQ=0.1.

(4) Rationale Codes:

Selection Reason: Above Screening Levels (ASL)
Deletion Reason: Below Screening Level (BSL)
Not Sufficiently Volatile (NSV)
No Toxicity Information (NTX)

ARAR/TBC = Applicable or Relevant and Appropriate Requirement/ To Be Considered
ca = carcinogenic
COPC = Chemical of Potential Concern
DNX = 1,3-Dinitro-5-nitroso-1,3,5-triazinane
HQ = hazard quotient
HMX = Hot Melt Explosive
J = compound was detected below the reporting limit in the sample
MNX = 1-Nitroso-3,5-dinitro-1,3,5-triazacyclohexane
NA = not available
nc = noncarcinogenic
RDX = Royal De µg/L= microgram per liter
TNX = Hexahydro-1,3,5-trinitroso-1,3,5-triazine

TABLE 2.5
OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN
West Burn Pads Area
Iowa Army Ammunition Plant, Middletown, Iowa

Scenario Timeframe: Future (Construction/Utility Worker)
Medium: Shallow Groundwater
Exposure Medium: Shallow Groundwater in a Trench

Exposure Point	CAS Number	Chemical	Minimum Concentration Qualifier	Maximum Concentration Qualifier	Units	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits	Concentration Used for Screening (1)	Background Value (2)	Screening Toxicity Value (3)	Potential ARAR/TBC Value (4)	Potential ARAR/TBC Source (4)	COPC Flag	Rationale for Selection or Deletion (5)

Notes:

(1) Maximum concentration is used for screening.

(2) Source: *Evaluation of Background Concentrations of Metals in Groundwater, Iowa Army* Ammunition Plant, *Middletown, Iowa*. Prepared for U.S. Army Corps of Engineers Louisville District (CH2M, February 2020).

(3) Regional Screening Levels (RSL) for Tap Water (May 2023). Concentrations based on non-carcinogenic health effects are based on HQ=0.1.

(4) Values are the Federal Maximum Contaminant Levels (MCLs) and if no MCL was available, the EPA's (March 2018) Office of Water Lifetime Health Advisory (LHA) was provided.

(5) Rationale Codes

Selection Reason: Above Screening Levels (ASL)
Deletion Reason: Below Screening Level (BSL)
No Toxicity Information (NTX)

ARAR/TBC = Applicable or Relevant and Appropriate Requirement/ To Be Considered
ca = carcinogenic
COPC = Chemical of Potential Concern
DNX = 1,3-Dinitro-5-nitroso-1,3,5-triazinane
HQ = hazard quotient
HMX = Hot Melt Explosive
J = compound was detected below the reporting limit in the sample
L = federal action level
MNX = 1-Nitroso-3,5-dinitro-1,3,5-triazacyclohexane
NA = not available
nc = noncarcinogenic
RDX = Royal Demolition Explosive
TNX = Hexahydro-1,3,5-trinitroso-1,3,5-triazine
μg/L= microgram per liter

Notes:
(1) Determination of EPCs for the COPCs within the RDX Plume are provide in Table 3.1.RME Supplement A
(2) Determination of EPCs for the COPCs within the West VOC Plume are provide in Table 3.1.RME Supplement B.
(3) Determination of EPCs for the COPCs within the East VOC Plume are provide in Table 3.1.RME Supplement C.
(4) The Final EPCs for Groundwater (Potable Use) are the highest EPC from the RDX, West VOC, and East VOC Plumes or the site-wide maximum detected concentration*.
*If the maximum detected concentration of a groundwater COPC was not in the subset of wells from the core of the RDX or VOC plumes, the maximum detected concentration of the COPC in the site-wide groundwater data set was used.

Statistics:
Gamma Adjusted KM-UCL: UCL based on Kaplan-Meier estimates adjusted assuming gamma distribution
KM (t): UCL based on Kaplan-Meier estimates using the Student's t-distribution critical value

Acronyms:
EPC = Exposure Point Concentration
NA = not applicable or not available
UCL = Upper Confidence Limit
ug/L = microgram per liter

TABLE 3.1.RME SUPPLEMENT A
MEDIUM-SPECIFIC EXPOSURE POINT CONCENTRATION SUMMARY
REASONABLE MAXIMUM EXPOSURE
West Burn Pad Area
Iowa Army Ammunition Plant, Middletown, Iowa

Scenario Timeframe: Future (Site Worker and Hypothetical Resident)
Medium: Groundwater (RDX Plume)
Exposure Medium: Tapwater

Exposure Point	Chemical of Potential Concern	Units	Arithmetic Mean*	95% UCL (Distribution)	Maximum Concentration (Qualifier)	Exposure Point Concentration **			
						Value	Units	Statistic	Rationale

Notes:
EPA's ProUCL software (June 2016, Version 5.1.002) used to determine distribution of data (normal, lognormal, gamma distribution, or nonparametric) and estimate upper confidence limits (UCLs).
* Arithmetic mean of detected concentrations are presented.
** Groundwater EPCs for explosives were calculated using monitoring wells located within the core of the RDX plume: JAW-23, JAW-25, JAW-68, WBP-99-1, WBP-99-2, WBP-99-4, WBP-99-5, WBP-99-6, WBP-MW1, WBP-MW3, WBP-MW6, WBP-MW8, WBP-MW9, WBP-TTMW-01, WBP-TTMW-02, WBP-TTMW-03, WBP-TTMW-05B, WBP-TTMW-06, WBP-TTMW-11, WBP-TTMW-12, WBP-TTMW-14, and WBP-TTMW-15.
If the maximum detected concentration of a groundwater COPC was not in the subset of wells from the core of the RDX plume, the maximum detected concentration of the COPC in the site-wide groundwater data set was used.

Statistics:
Gamma Adjusted KM-UCL: UCL based on Kaplan-Meier estimates adjusted assuming gamma distribution
KM (t): UCL based on Kaplan-Meier estimates using the Student's t-distribution critical value

Rationale:
(1) The maximum detected concentration was used as the EPC because there were less than 4 detected concentrations or less than 8 samples were collected.
(2) Distribution tests are inconclusive; therefore, the nonparametric UCL was used as the EPC.
(3) Anderson-Darling and/or Kolmogorov-Smirnov Tests indicate data are gamma distributed.

Acronyms:
EPC = Exposure Point Concentration
G = Gamma distribution
J = chemical was detected below the reporting limit in the sample
NA = not applicable or not available
UCL = Upper Confidence Limit
ug/L = microgram per liter

(1) Site-specific.

VDEQ. Virginia Unified Risk Assessment Model. Appendix 3 Construction Worker Groundwater Trench Model. 2018.

$C_{trench} = C_{GW} \times VF$

C_{trench} = concentration of contaminant in the trench (ug/m^3)

C_{GW} = concentration of contaminant in groundwater (ug/L)

VF = volatilization factor (L/m^3)

TABLE 3.3 RME SUPPLEMENT A

Calculation of Constituent Concentrations in Air from Trench Water Using VDEQ Model

West Burn Pad Area

Iowa Army Ammunition Plant, Middletown, Iowa

For Mass-Transfer Coefficients

Kg,H_2O	0.833	cm/s
MWH_2O	18	
Kl,O_2	0.002	cm/s
MWO_2	32	
T	**70**	F
T	294	K
R	8.20E-05	atm-m^3/mol-K

For Emission Flux and Concentration in Trench

CF1	1.00E-03	L/cm^3
CF2	1.00E+04	cm^2/m^2
CF3	3600	s/hr
F	**1**	
ACH	2	hr^{-1}

Trench dimensions

Length	**8**	ft
	2.44	m
Width	**2.99**	ft
	0.91	m
Depth	**8**	ft
	2.44	m
Width/Depth	0.37	

VF = (K_i x A x F x 10^{-3} x 10^4 x 3600) / (ACH x V)
K_i = overall mass transfer coefficient of contaminant (cm/sec)
A = area of trench (m^2)
F = fraction of floor through which contaminant can enter (unitless)
ACH = air changes per hour (h^{-1})
V = volume of trench (m^3)
10^{-3} = conversion factor (L/cm^3)
10^4 = conversion factor (cm^2/m^2)
3600 = conversion factor (sec/hr)

Ki = 1 / {(1/kiL) + [(R T) / (Hi k_{iG})]}
kiL = liquid-phase mass transfer coefficient of i (cm/sec)
R = ideal gas constant (8.2 x 10^{-5} atm-m^3/mole-K)
T = average system Fahrenheit (F); average site groundwater temperature (68 F or 20 Celsius).
T = average system absolute temperature (298 K)
Hi = Henry's Law constant of i (atm-m^3/mol) from EPA Regional Screening Levels tables (May 2023)
k_{ig} = gas-phase mass transfer coefficient of i (cm/sec)

kiL = (MWO_2/MWi)0.5 x (T/298) x kL,O_2 (cm/sec)
MWO_2 = molecular weight of O_2 (g/mol)
MWi = molecular weight of component i (g/mol)
kL, O_2 = liquid-phase mass transfer coefficient of oxygen at 25oC (0.002 cm/sec)

k_{iG} = (MWH_2O/MWi)0.335 x (T/298)1.005 x kG, H_2O (cm/s)
MWH_2O = molecular weight of water (g/mol)
k_g, H_2O = gas-phase mass transfer coefficient of water vapor at 25oC (0.833 cm/sec)

TABLE 3.3.RME SUPPLEMENT B
MEDIUM-SPECIFIC EXPOSURE POINT CONCENTRATION SUMMARY
REASONABLE MAXIMUM EXPOSURE
West Burn Pad Area
Iowa Army Ammunition Plant, Middletown, Iowa

Scenario Timeframe: Future (Construction/Utility Worker)
Medium: Shallow Groundwater (RDX Plume)
Exposure Medium: Shallow Groundwater/Trench Air

Exposure Point	Chemical of Potential Concern	Units	Arithmetic Mean*	95% UCL (Distribution)	Maximum Concentration (Qualifier)		Exposure Point Concentration **

	Trichloroethene	µg/L	7.7E+00	NA	5.4E+01	J	5.4E+01	µg/L	Plume Max	1

Notes:
EPA's ProUCL software (June 2016, Version 5.1.002) used to determine distribution of data (normal, lognormal, gamma distribution, or nonparametric) and estimate upper confidence limits (UCLs).
* Arithmetic mean of detected concentrations are presented.
** Groundwater EPCs for explosives were calculated using monitoring wells located within the core of the RDX plume: JAW-23, JAW-25, WBP-MW1, WBP-TTMW-01, WBP-TTMW-02, WBP-TTMW-03, WBP-TTMW-05B, WBP-TTMW-11, and WBP-TTMW-14.
If the maximum detected concentration of a groundwater COPC was not in the subset of wells from the core of the RDX plume, the maximum detected concentration of the COPC in the site-wide groundwater data set was used.

Statistics:
KM (t): UCL based on Kaplan-Meier estimates using the Student's t-distribution critical value

Rationale:
(1) The maximum detected concentration was used as the EPC because there were less than 4 detected concentrations or less than 8 samples were collected.
(2) Distribution tests are inconclusive; therefore, the nonparametric UCL was used as the EPC.
(3) The maximum detected concentration was used as the EPC because the UCL exceeds the maximum.

Acronyms:
EPC = Exposure Point Concentration
J = chemical was detected below the reporting limit in the sample
NA = not applicable or not available
UCL = Upper Confidence Limit
ug/L = microgram per liter

Notes:

(1) This value is the upper confidence limit on the mean water ingestion rate while splashing, which is the type of activity expected if a worker has contact with shallow groundwater while performing repairs or maintenance activities on a culvert [Table 3-96 of the Exposure Factors Handbook (EPA, 2019)].

(2) Professional judgment assuming a worker would have contact with shallow groundwater while performing repairs or maintenance activities on a culvert for 1 hour a day, 6 days a week for 2 weeks per year.

(3) Calculated as the product of ED (years) x 365 days/year.

(4) Calculated as the product of 70 years assumed human lifetime (EPA, 2014) x 365 days/year.

(5) Skin surface area in contact with shallow groundwater assumed to be head, hands, forearms, lower legs, and feet (EPA, 2011).

Note:

(1) Source: Risk Assessment Guidance for Superfund. Volume 1: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. Section 4.2 and Exhibit 4-1. USEPA recommends that the oral RfD should not be adjusted to estimate the absorbed dose for compounds when the absorption efficiency is greater than 50%. Constituents that do not have oral absorption efficiencies reported on this table were assumed to have an oral absorption efficiency of 100%.

(2) Adjusted based on RAGS Part E.

(3) The RfD for xylenes was used for m,p-xylene and o-xylene.

CANCER TOXICITY DATA -- ORAL/DERMAL

West Bun Pit Area

Iowa Army Ammunition Plant, Middletown, Iowa

Chemical of Potential Concern	Oral Cancer Slope Factor		Oral Absorption Efficiency for Dermal (1)	Absorbed Cancer Slope Factor for Dermal (2)		Weight of Evidence/ Cancer Guideline Description	Oral CSF	
	Value	Units		Value	Units		Source(s)	Date(s) (MM/DD/YYYY)

(1) Source: Risk Assessment Guidance for Superfund. Volume 1: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. Section 4.2 and Exhibit 4-1. USEPA recommends that the oral slope factor should not be adjusted to estimate the absorbed dose for compounds when the absorption efficiency is greater than 50%. Constituents that do not have oral absorption efficiencies reported on this table were assumed to have an oral absorption efficiency of 100%.

(2) Adjusted based on RAGS Part E.

(3) This chemical operates with a mutagenic mode of action (EPA, 2005) and would exhibit a greater effect in early-life versus later-life exposure. With the exception of vinyl chloride, chemical-specific toxicity data are not available for childhood and early-life exposures; thus, EPA (2005) default age-dependent adjustment factors (ADAF) will be applied to the slope factor as follows:

AGE	AGE ADAF
0-<2	10
2-<16	3
16-<26	1

Definitions:
Cal EPA = California Environmental Protection Agency
IRIS = Integrated Risk Information System
PPRTV = Provisional Peer-Reviewed Toxicity Value
NA = Not Available

Weight of Evidence definitions (EPA, 1986):

Group A chemicals (known human carcinogens) are agents for which there is sufficient evidence to support the causal association between exposure to the agents in humans and cancer.

Group B1 chemicals (probable human carcinogens) are agents for which there is limited evidence of possible carcinogenicity in humans.

Group B2 chemicals (probable human carcinogens) are agents for which there is sufficient evidence of carcinogenicity in animals but inadequate or a lack of evidence in humans.

Group C chemicals (possible human carcinogens) are agents for which there is limited evidence of carcinogenicity in animals and inadequate or a lack of human data.

Group D chemicals (not classifiable as to human carcinogenicity) are agents with inadequate human and animal evidence of carcinogenicity or for which no data are available.

Inorganics: DAevent (mg/cm^2-event) =

DA_{event} = Kp x CW x tevent x 0.001 mg/ug x 0.001 l/cm^3 (Eq 1)

Organics: DAevent (mg/cm^2-event) =

DA_{event} = $t_{event} \leq t^*$: DA_{event} (mg/cm^2-event) =
2 x FA x Kp x Cw x (sqrt((6 x τ x t_{event}) / (3.1415))) x CF1 x CF2 (Eq 2)

$t_{event} > t^*$: DA_{event} (mg/cm^2-event) =
FA x Kp x CW x (t_{event}/(1+B) + 2 x τ x ((1 + 3B + 3B^2)/(1+B)^2)) xCF1 x CF2 (Eq 3)

Notes:
Values for permeability constants, B, tau, t*, and FA are from EPA 2004, *Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment - Final).* EPA/540/R/99/005.
B - Dimensionless ratio of the permeability coefficient of a compound through the stratum corneum relative to its permeability coefficient across the viable epidermis (dimensionless).
cm/hr - centimeter per hour
hr - hour
mg/cm^2-event - milligram per square centimeter per event
µg/L - microgram per liter
NA - Not applicable
t* - Time to reach steady-state
CF1 - Conversion Factor 1 (0.001 mg/µg), CF2 - Conversion Factor 2 (0.001 L/cm^3)

Inorganics: DAevent (mg/cm^2-event) =

DA_{event} = Kp x CW x tevent x 0.001 mg/ug x 0.001 l/cm^3 (Eq 1)

Organics: DAevent (mg/cm^2-event) =

DA_{event} = $t_{event} \leq t^*$: DA_{event} (mg/cm^2-event) =
2 x FA x Kp x Cw x (sqrt((6 x τ x t_{event}) / (3.1415))) x CF1 x CF2 (Eq 2)

Notes:
Values for permeability constants, B, tau, t*, and FA are from EPA 2004, *Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment - Final).* EPA/540/R/99/005.
B - Dimensionless ratio of the permeability coefficient of a compound through the stratum corneum relative to its permeability coefficient across the viable epidermis (dimensionless).
cm/hr - centimeter per hour
hr - hour
mg/cm^2-event - milligram per square centimeter per event
µg/L - microgram per liter
NA - Not applicable
t* - Time to reach steady-state
CF1 - Conversion Factor 1 (0.001 mg/µg), CF2 - Conversion Factor 2 (0.001 L/cm^3)

			Exp. Route Total								6E-05

Notes:

(1) Carcinogenic risks were estimated for trichloroethene by summing the risks for two different approaches: 1) Using the oral CSF factor for kidney cancer, which has a mutagenic mode of action (calculated in Table 7.3 RME Supplement A), and 2) using the CSF for non-Hodgkin lymphoma (NHL) and liver cancer.

(2) Intakes and exposure concentrations using the toxicity values for the kidney component of TCE were estimated on Table 7.3 RME Supplement A.

CSF = Cancer slope factor

µg/L = microgram per liter

mg/m^3= milligram per cubic meter

mg/kg/day = milligram per kilogram per day

Inorganics: DAevent (mg/cm^2-event) =

DA_{event} = Kp x CW x tevent x 0.001 mg/ug x 0.001 l/cm^3 (Eq 1)

Organics: DAevent (mg/cm^2-event) =

DA_{event} = $t_{event} \leq t^*$: DA_{event} (mg/cm^2-event) =
2 x FA x Kp x Cw x (sqrt((6 x τ x t_{event}) / (3.1415))) x CF1 x CF2 (Eq 2)

Notes:
Values for permeability constants, B, tau, t*, and FA are from EPA 2004, *Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment - Final).* EPA/540/R/99/005.
B - Dimensionless ratio of the permeability coefficient of a compound through the stratum corneum relative to its permeability coefficient across the viable epidermis (dimensionless).
cm/hr - centimeter per hour
hr - hour
mg/cm^2-event - milligram per square centimeter per event
µg/L - microgram per liter
NA - Not applicable
t* - Time to reach steady-state
CF1 - Conversion Factor 1 (0.001 mg/µg), CF2 - Conversion Factor 2 (0.001 L/cm^3)

Inorganics: DAevent (mg/cm^2-event) =

DA_{event} = Kp x CW x tevent x 0.001 mg/ug x 0.001 l/cm^3 (Eq 1)

Organics: DAevent (mg/cm^2-event) =

DA_{event} = $t_{event} \leq t^*$: DA_{event} (mg/cm^2-event) =
2 x FA x Kp x Cw x (sqrt((6 x τ x t_{event}) / (3.1415))) x CF1 x CF2 (Eq 2)

Notes:
Values for permeability constants, B, tau, t*, and FA are from EPA 2004, *Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment - Final).* EPA/540/R/99/005.
B - Dimensionless ratio of the permeability coefficient of a compound through the stratum corneum relative to its permeability coefficient across the viable epidermis (dimensionless).
cm/hr - centimeter per hour
hr - hour
mg/cm^2-event - milligram per square centimeter per event
µg/L - microgram per liter
NA - Not applicable
t* - Time to reach steady-state
CF1 - Conversion Factor 1 (0.001 mg/µg), CF2 - Conversion Factor 2 (0.001 L/cm^3)

			Exp. Route Total								6E-05

Notes:

(1) Carcinogenic risks were estimated for trichloroethene by summing the risks for two different approaches: 1) Using the oral CSF factor for kidney cancer, which has a mutagenic mode of action (calculated in Table 7.8 RME Supplement A), and 2) using the CSF for non-Hodgkin lymphoma (NHL) and liver cancer.

(2) Intakes and exposure concentrations using the toxicity values for the kidney component of TCE were estimated on Table 7.8 RME Supplement A.

CSF = Cancer slope factor

µg/L = microgram per liter

mg/m^3= milligram per cubic meter

mg/kg/day = milligram per kilogram per day
